void *HeapMgr_malloc(size_t uiBytes)

(1) If this is the first call of HeapMgr_malloc(), then initialize the heap manager.

(2) Determine the number of units the new chunk should contain.

(3) For each bin from the start bin to the last bin...

   For each chunk in the current bin...
   
   If the current chunk is big enough and close to the requested size, then remove it from its bin, set its status to INUSE, and return it. If the current chunk is too big, then remove it from its bin, split the chunk, insert the front end of it into the proper bin, set the status of the tail end of it to INUSE, and return the tail end of it.

(4) Ask the OS for more memory, and create a new chunk from it. Insert the new chunk into the proper bin. If appropriate, coalesce the new chunk and the previous one in memory. To do so, remove both chunks from their bins, coalesce them to form a larger chunk, and insert the larger chunk into the proper bin. Let the current chunk be the new chunk.

(5) If the current chunk is big enough and close to the requested size, then remove it from its bin, set its status to INUSE, and return it. If the current chunk is too big, then remove it from its bin, split the chunk, insert the front end of it into the proper bin, set the status of the tail end of it to INUSE, and return the tail end of it.

(6) Return NULL.

void HeapMgr_free(void *pvBytes)

(1) Set the status of the given chunk to FREE.

(2) Insert the given chunk into the proper bin.

(3) If appropriate, coalesce the given chunk and the previous one in memory. To do so, remove both chunks from their bins, coalesce them to form a larger chunk, and insert the larger chunk into the proper bin.

(4) If appropriate, coalesce the given chunk and the next one in memory. To do so, remove both chunks from their bins, coalesce them to form a larger chunk, and insert the larger chunk into the proper bin.
