Mergesort

Mergesort and Quicksort

Two great sorting algorithms.

- Full scientific understanding of their properties has enabled us to
- hammer them into practical system sorts.
- Occupies a prominent place in world's computational infrastructure.
- Quicksort honored as one of top 10 algorithms for science and engineering of 20th century.

Mergesort.

- Java sort for objects.
- Perl stable, Python stable.

Quicksort.

- Java sort for primitive types.
- C qsort, Unix, q++, Visual C++, Perl, Python.

Mergesort

Mergesort.

- Divide array into two halves.
- Recursively sort each half.
- Merge two halves to make sorted whole.

Mergesort: Example

Mergesort: Java Implementation

```
I m
10 11 12 13 14 15 16 17 18 19
```

Merging

Merging. Combine two pre-sorted lists into a sorted whole.

How to merge efficiently? Use an auxiliary array.

```
aux A G L O R H I M S T

k

A G H I L M
```

Mergesort Analysis: Memory

- Q. How much memory does mergesort require?
- Original input array = N.
- Auxiliary array for merging = N.
- Local variables: constant.
- Function call stack: log₂ N.
- Total = 2N + O(log N).
- Q. How much memory do other sorting algorithms require?
- ullet N + O(1) for insertion sort and selection sort.
- In-place = $N + O(\log N)$.

Challenge for the bored. In-place merge. [Kronrud, 1969]

Mergesort Analysis: Running Time

Def. T(N) = number of comparisons to mergesort an input of size N.

Mergesort recurrence.

$$T(N) \le \left\{ \underbrace{\frac{0}{T(\lceil N/2 \rceil)}}_{\text{solve left half}} + \underbrace{\frac{T(\lceil N/2 \rceil)}{\text{solve right half}}}_{\text{solve right half}} + \underbrace{\frac{N}{N}}_{\text{merging}} \right\} \text{ otherwise}$$

including already sorted

Solution. $T(N) = O(N \log_2 N)$.

- Note: same number of comparisons for any input of size N.
- We prove $T(N) = N \log_2 N$ when N is a power of 2, and = instead of \leq .

Proof by Induction

Claim. If T(N) satisfies this recurrence, then $T(N) = N \log_2 N$.

assumes N is a power of 2

$$T(N) = \begin{cases} 0 & \text{if } N = 1\\ \underbrace{2T(N/2)}_{\text{sorting both halves}} + \underbrace{N}_{\text{merging}} & \text{otherwise} \end{cases}$$

Pf. (by induction on n)

- Base case: n = 1.
- Inductive hypothesis: $T(n) = n \log_2 n$.
- Goal: show that T(2n) = 2n log₂ (2n).

$$T(2n) = 2T(n) + 2n$$

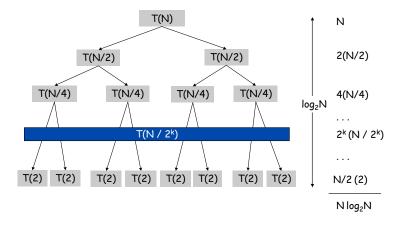

$$= 2n\log_2 n + 2n$$

$$= 2n(\log_2(2n) - 1) + 2n$$

$$= 2n\log_2(2n)$$

Proof by Recursion Tree

$$T(N) = \begin{cases} 0 & \text{if } N = 1\\ \underbrace{2T(N/2)}_{\text{sorting both halves}} + \underbrace{N}_{\text{merging}} & \text{otherwise} \end{cases}$$

Mergesort: Practical Improvements

Use sentinel. Two statements in inner loop are array-bounds checking.

Use insertion sort on small subarrays.

- Mergesort has too much overhead for tiny subarrays.
- Cutoff to insertion sort for ≈ 7 elements.

Stop if already sorted.

- Is biggest element in first half ≤ smallest element in second half?
- Helps for nearly ordered lists.

Eliminate the copy to the auxiliary array. Save time (but not space) by switching the role of the input and auxiliary array in each recursive call.

Sorting Analysis Summary

Running time estimates:

- Home pc executes 10⁸ comparisons/second.
- Supercomputer executes 10¹² comparisons/second.

Insertion Sort (N2)

instant	instant	instant

Lesson 1. Good algorithms are better than supercomputers.

-

Quicksort

Quicksort.

- Shuffle the array.
- Partition array so that:
 - element a[i] is in its final place for some i
 - no larger element to the left of ${\tt i}$
 - no smaller element to the right of i
- Sort each piece recursively.
- ${\sf Q}.$ How do we partition in-place efficiently?

  int j = r;
   while(true) {
                                       find item on left to swap
     while (less(a[++i], a[r]))
     if (i == r) break;
     while (less(a[r], a[--j]))
                                       find item on right to swap
     if (j == 1) break;
      if (i >= j) break;
      exch(a, i, j);
                         swap with partitioning element
   exch(a, i, r);
   return i;
                           return index where crossing occurs
```

Quicksort Implementation Details

Partitioning in-place. Using a spare array makes partitioning easier, but is not worth the cost.

Terminating the loop. Testing whether the pointers cross is a bit trickier than it might seem.

Staying in bounds. The (i == r) test is redundant, but the (j == 1) test is not.

Preserving randomness. Shuffling is key for performance guarantee.

Equal keys. When duplicates are present, it is (counter-intuitively) best to stop on elements equal to partitioning element.

Quicksort: Performance Characteristics

Worst case. Number of comparisons is quadratic.

N + (N-1) + (N-2) + ... + 1 = N(N+1)/2

• More likely that your computer is struck by lightning.

Caveat. Many textbook implementations go quadratic if input:

- Is sorted.
- Is reverse sorted.
- Has many duplicates.

Quicksort: Average Case

Theorem. The average number of comparisons C_N to quicksort a random file of N elements is about $2N \ln N$.

■ The precise recurrence satisfies $C_0 = C_1 = 0$ and for $N \ge 2$:

$$C_{N} = N + 1 + \frac{1}{N} \sum_{k=1}^{N} (C_{k} + C_{N-k})$$
$$= N + 1 + \frac{2}{N} \sum_{k=1}^{N} C_{k-1}$$

 \blacksquare Multiply both sides by N and subtract the same formula for N-1:

$$NC_N - (N-1)C_{N-1} = N(N+1) - (N-1)N + 2C_{N-1}$$

Simplify to:

$$NC_N = (N+1) C_{N-1} + 2N$$

Quicksort: Average Case

Average case running time.

- Roughly 2 N In N comparisons. ← see next two slides
- Assumption: file is randomly shuffled.

Remarks.

- 39% more comparisons than mergesort.
- Faster than mergesort in practice because of lower cost of other high-frequency instructions.
- Caveat: many textbook implementations have best case N² if duplicates, even if randomized!

Quicksort: Average Case

■ Divide both sides by N(N+1) to get a telescoping sum:

$$\frac{C_N}{N+1} = \frac{C_{N-1}}{N} + \frac{2}{N+1}$$

$$= \frac{C_{N-2}}{N-1} + \frac{2}{N} + \frac{2}{N+1}$$

$$= \frac{C_{N-3}}{N-2} + \frac{2}{N-1} + \frac{2}{N} + \frac{2}{N+1}$$

$$= \vdots$$

$$= \frac{C_2}{3} + \sum_{k=3}^{N} \frac{2}{k+1}$$

Approximate the exact answer by an integral:

$$\frac{C_N}{N+1} \approx \sum_{k=1}^{N} \frac{2}{k} \approx \int_{k=1}^{N} \frac{2}{k} = 2 \ln N$$

• Finally, the desired result:

$$C_N \approx 2(N+1) \ln N \approx 1.39 N \log_2 N$$
.

Lesson 1. Good algorithms are better than supercomputers.

Lesson 2. Great algorithms are better than good ones.

Duplicate Keys

Equal keys: omnipresent in applications when purpose of sort is to bring records with equal keys together.

- Sort population by age.
- Finding collinear points.
- Remove duplicates from mailing list.
- Sort job applicants by college attended.

Typical application.

- Huge file.
- Small number of key values.
- Randomized 3-way quicksort is LINEAR time. (Try it!)

Theorem. Quicksort with 3-way partitioning is optimal.

Pf. Ties cost to entropy. Beyond scope of 226.

Quicksort: Practical Improvements

Median of sample.

- Best choice of pivot element = median.
- But how would you compute the median?
- Estimate true median by taking median of sample.

Insertion sort small files.

- Even quicksort has too much overhead for tiny files.
- Can delay insertion sort until end.

Optimize parameters.

- Median of 3 elements.
- Cutoff to insertion sort for \approx 10 elements.

Non-recursive version.

■ Use explicit stack.

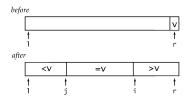

guarantees O(log N) stack size

Always sort smaller half first.

3-Way Partitioning

3-way partitioning. Partition elements into 3 parts:

- Elements between i and j equal to partition element v.
- No larger elements to left of i.
- No smaller elements to right of j.

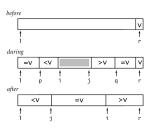

Dutch national flag problem.

- Not done in practical sorts before mid-1990s.
- Incorporated into Java system sort, C qsort.

Dutch National Flag Problem: Solution

Solution to Dutch national flag problem.

- Partition elements into 4 parts:
 - no larger elements to left of i
 - no smaller elements to right of j
 - equal elements to left of p
 - equal elements to right of q
- Afterwards, swap equal keys into center.

All the right properties.

- In-place.
- Not much code.
- Linear if keys are all equal.
- Small overhead if no equal keys.

Selection

Selection. Find the kth largest element.

Min: k = 1.
Max: k = N.
Median: k = N/2.

Easy. Min or max with O(N) comparisons; median with $O(N \log N)$.

Challenge. O(N) comparisons for any k.

3-way Quicksort: Java Implementation

```
private static void sort(Comparable[] a, int 1, int r) {
   if (r <= 1) return;</pre>
   int i = 1-1, j = r;
   int p = 1-1, q = r;
                                               4-way partitioning
   while(true) {
      while (less(a[++i], a[r])) ;
      while (less(a[r], a[--j])) if (j == 1) break;
      if (i >= j) break;
      exch(a, i, j);
      if (eq(a[i], a[r])) exch(a, ++p, i);
     if (eq(a[j], a[r])) exch(a, --q, j);
                               swap equal keys to left or right
   exch(a, i, r);
                               swap equal keys back to middle
   j = i - 1;
   i = i + 1;
   for (int k = 1; k \le p; k++) exch(a, k, j--);
   for (int k = r-1; k >= q; k--) exch(a, k, i++);
   sort(a, 1, j);
                     recursively sort left and right piece
   sort(a, i, r);
```

Selection

Quick select.

- Partition array so that:
 - element a[i] is in its final place for some i
 - no larger element to the left of i
 - no smaller element to the right of i
- Repeat in one subarray, depending on i.

```
public static void select(Comparable[] a, int k) {
   Random.shuffle(a);
   int 1 = 0;
   int r = a.length - 1;
   while (r > 1) {
      int i = partition(a, 1, r);
      if (i > k) r = i - 1;
      else if (i < k) 1 = i + 1;
      else return;
   }
}</pre>
```

hattishildi kildista datishildi hattishildi kilosta batishildi attishildi kilosta datishildi aasaalii kilosta datishildi aasaalii datishildi aasaalii datishildi

Quick-Select Analysis

Property C. Quick-select takes linear time on average.

- Intuitively, each partitioning step roughly splits array in half.
- N + N/2 + N/4 + ... < 2N comparisons.
- Formal analysis similar to quicksort analysis proves the average number of comparisons is

$$2N + k \ln\left(\frac{N}{k}\right) + (N-k) \ln\left(\frac{N}{N-k}\right)$$

Ex: (2 + 2 ln 2) N comparisons to find the median

Worst-case. The worst-case is $\Omega(N^2)$ comparisons, but as with quicksort, the random shuffle makes this case extremely unlikely.
