- ▶ iterators
- ▶ Comparable keys
- ▶ challenges

2

## Symbol Tables

Key-value pair abstraction.

- **Insert** a value with specified key.
- Given a key, **search** for the corresponding value.

Example: **DNS lookup**.

- Insert URL with specified IP address.
- Given URL, find corresponding IP address

URL	IP address
<a href="http://www.cs.princeton.edu">www.cs.princeton.edu</a>	128.112.136.11
<a href="http://www.princeton.edu">www.princeton.edu</a>	128.112.128.15
<a href="http://www.yale.edu">www.yale.edu</a>	130.132.143.21
<a href="http://www.harvard.edu">www.harvard.edu</a>	128.103.060.55
<a href="http://www.simpsons.com">www.simpsons.com</a>	209.052.165.60

key

value

Can interchange roles: given IP address find corresponding URL

3

## Symbol Table Applications

Application	Purpose	Key	Value
Phone book	Look up phone number	Name	Phone number
Bank	Process transaction	Account number	Transaction details
File share	Find song to download	Name of song	Computer ID
File system	Find file on disk	Filename	Location on disk
Dictionary	Look up word	Word	Definition
Web search	Find relevant documents	Keyword	List of documents
Book index	Find relevant pages	Keyword	List of pages
Web cache	Download	Filename	File contents
Genomics	Find markers	DNA string	Known positions
DNS	Find IP address given URL	URL	IP address
Reverse DNS	Find URL given IP address	IP address	URL
Compiler	Find properties of variable	Variable name	Value and type
Routing table	Route Internet packets	Destination	Best route

4

## Symbol Table API

**Associative array** abstraction: Unique value associated with each key.

```
public class *ST<Key extends Comparable<Key>, Value>
{
    *ST()                create a symbol table
    void put(Key key, Value val) put key-value pair into the table ← insert
    Value get(Key key)      return value paired with key           ← search
                          (null if key not in table)
    boolean contains(Key key) is there a value paired with key?
    void remove(Key key)    remove key-value pair from table      ← stay tuned
    Iterator<Key> iterator() iterator through keys in table
}
```

Our conventions:

1. Values are not `null`.
2. Method `get()` returns `null` if key not present

enables this code in all implementations:

```
public boolean contains(Key key)
{ return get(key) != null; }
```

3. Method `put()` overwrites old value with new value.

`a[key] = val;` ← Some languages (not Java) allow this notation

5

## ST client: make a dictionary and process lookup requests

Command line arguments

- a comma-separated value (CSV) file
- key field
- value field

Example 1: DNS lookup

```
% java Lookup ip.csv 0 1
adobe.com
192.150.18.60
www.princeton.edu
128.112.128.15
ebay.edu
Not found

% java Lookup ip.csv 1 0
128.112.128.15
www.princeton.edu
999.999.999.99
Not found
```

URL is key IP is value

IP is key URL is value

```
% more ip.csv

## ST client: make a dictionary and process lookup requests

```
public class Lookup
{
    public static void main(String[] args)
    {
        In in = new In(args[0]);
        int keyField = Integer.parseInt(args[1]);
        int valField = Integer.parseInt(args[2]);
        String[] database = in.readAll().split("\n");

        ST<String, String> st = new ST<String, String>();
        for (int i = 0; i < database.length; i++)
        {
            String[] tokens = database[i].split(",");
            String key = tokens[keyField];
            String val = tokens[valField];
            st.put(key, val);
        }

        while (!StdIn.isEmpty())
        {
            String s = StdIn.readString();
            if (!st.contains(s)) StdOut.println("Not found");
            else StdOut.println(st.get(s));
        }
    }
}
```

← process input file

← build symbol table

← process lookups with standard I/O

7

## ST client: make a dictionary and process lookup requests

Command line arguments

- a comma-separated value (CSV) file
- key field
- value field

Example 2: Amino acids

```
% java Lookup amino.csv 0 3
ACT
Threonine
TAG
Stop
CAT
Histidine
```

codon is key name is value

```
% more amino.csv
TTT,Phe,F,Phenylalanine
TTC,Phe,F,Phenylalanine
TTA,Leu,L,Leucine
TTG,Leu,L,Leucine
TCT,Ser,S,Serine
TCC,Ser,S,Serine

9

## Keys and Values

### Associative array abstraction.

`a[key] = val;`

- Unique value associated with each key
- If client presents duplicate key, overwrite to change value.

### Key type: several possibilities

1. Assume keys are any generic type, use `equals()` to test equality.
2. Assume keys are `Comparable`, use `compareTo()`.
3. Use `equals()` to test equality and `hashCode()` to scramble key.

### Value type. Any generic type.

### Best practices. Use immutable types for symbol table keys.

- Immutable in Java: `String`, `Integer`, `BigInteger`.
- Mutable in Java: `Date`, `GregorianCalendar`, `StringBuilder`.

10

## Elementary ST implementations

Unordered array  
Ordered array  
Unordered linked list  
Ordered linked list

### Why study elementary implementations?

- API details need to be worked out
- performance benchmarks
- method of choice can be one of these in many situations
- basis for advanced implementations

Always good practice to study elementary implementations

11

- API
- basic implementations
- iterators
- Comparable keys
- challenges

12

## Unordered array ST implementation

Maintain **parallel arrays** of keys and values.

Instance variables

- array **keys[]** holds the keys.
- array **vals[]** holds the values.
- integer **N** holds the number of entries.

Need to use standard array-doubling technique

**N = 6**  
↓

	0	1	2	3	4	5
<b>keys[]</b>	it	was	the	best	of	times
<b>vals[]</b>	2	2	1	1	1	1

Alternative: define inner type for entries

- space overhead for entry objects
- more complicated code

13

## Unordered array ST implementation (skeleton)

```
public class UnorderedST<Key, Value>
{
    private Value[] vals;
    private Key[] keys;
    private int N = 0;

    public UnorderedST(int maxN)
    {
        keys = (Key[]) new Object[maxN];
        vals = (Value[]) new Object[maxN];
    }

    public boolean isEmpty()
    {
        return N == 0;
    }

    public void put(Key key, Value val)
    {
        // see next slide
    }

    public Value get(Key key)
    {
        // see next slide
    }
}
```

← parallel arrays lead to cleaner code than defining a type for entries

← standard array doubling code omitted

← standard ugly casts

14

## Unordered array ST implementation (search)

```
public Value get(Key key)
{
    for (int i = 0; i < N; i++)
        if (keys[i].equals(key))
            return vals[i];
    return null;
}
```

	0	1	2	3	4	5
<b>keys[]</b>	it	was	the	best	of	times
<b>vals[]</b>	2	2	1	1	1	1

↑ ↑ ↑  
get("the") returns 1

	0	1	2	3	4	5
<b>keys[]</b>	it	was	the	best	of	times
<b>vals[]</b>	2	2	1	1	1	1

↑ ↑ ↑ ↑ ↑ ↑  
get("worst") returns null

Key, Value are generic and can be **any** type

← Java convention: all objects implement equals()

15

## Unordered array ST implementation (insert)

```
public void put(Key key, Value val)
{
    int i;
    for (i = 0; i < N; i++)
        if (key.equals(keys[i]))
            break;
    vals[i] = val;
    keys[i] = key;
    if (i == N) N++;
}
```

	0	1	2	3	4	5
<b>keys[]</b>	it	was	the	best	of	times
<b>vals[]</b>	2	2	1	1	1	1

↑ ↑ ↑  
put("the", 2) overwrites the 1

	0	1	2	3	4	5	6
<b>keys[]</b>	it	was	the	best	of	times	worst
<b>vals[]</b>	2	2	2	1	1	1	1

↑ ↑ ↑ ↑ ↑ ↑ ↑  
put("worst", 1) adds a new entry

Associative array abstraction

- must** search for key and overwrite with new value if it is there
- otherwise, add new key, value at the end (as in stack)

16

## Java conventions for equals()

All objects implement equals() but default implementation is (x == y)

Customized implementations.

String, URL, Integer.

User-defined implementations.

Some care needed (example: type of argument must be Object)

Equivalence relation. For any references x, y and z:

- Reflexive: x.equals(x) is true.
- Symmetric: x.equals(y) iff y.equals(x).
- Transitive: If x.equals(y) and y.equals(z), then x.equals(z).
- Non-null: x.equals(null) is false.
- Consistency: Multiple calls to x.equals(y) return same value.

17

## Implementing equals()

Seems easy

```
public class PhoneNumber
{
    private int area, exch, ext;
    ...
    public boolean equals(PhoneNumber y)
    {
        PhoneNumber a = this;
        PhoneNumber b = (PhoneNumber) y;
        return (a.area == b.area)
            && (a.exch == b.exch)
            && (a.ext == b.ext);
    }
}
```

18

## Implementing equals()

Seems easy, but requires some care

```
public final class PhoneNumber
{
    private final int area, exch, ext;
    ...
    public boolean equals(Object y)
    {
        if (y == this) return true;
        if (y == null) return false;
        if (y.getClass() != this.getClass())
            return false;

        PhoneNumber a = this;
        PhoneNumber b = (PhoneNumber) y;
        return (a.area == b.area)
            && (a.exch == b.exch)
            && (a.ext == b.ext);
    }
}
```

no safe way to use with inheritance

Must be Object.  
Why? Experts still debate.

Optimize for true object equality

If I'm executing this code,  
I'm not null.

Objects must be in the same class.

19

## Linked list ST implementation

Maintain a linked list with keys and values.

inner Node class

- instance variable key holds the key
- instance variable val holds the value

instance variable

- Node first refers to the first node in the list

20

## Linked list ST implementation (skeleton)

```
public class LinkedListST<Key, Value>
{
    private Node first; // instance variable

    private class Node // inner class
    {
        Key key;
        Value val;
        Node next;
        Node(Key key, Value val, Node next)
        {
            this.key = key;
            this.val = val;
            this.next = next;
        }
    }

    public void put(Key key, Value val)
    // see next slides

    public Val get(Key key)
    // see next slides
}
```

21

## Linked list ST implementation (search)

```
public Value get(Key key)
{
    for (Node x = first; x != null; x = x.next)
        if (key.equals(x.key))
            return vals[i];
    return null;
}
```

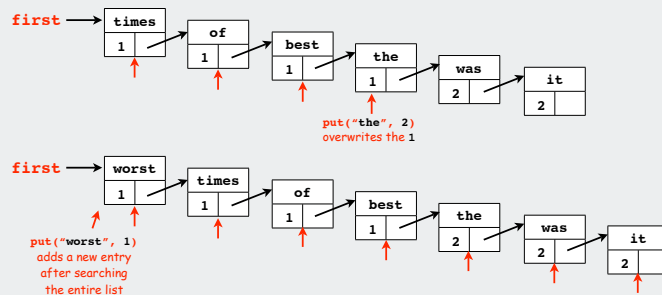

22

## Linked list ST implementation (insert)

```
public void put(Key key, Value val)
{
    for (Node x = first; x != null; x = x.next)
        if (key.equals(x.key))
            { x.value = value; return; }
    first = new Node(key, value, first);
}
```

### Associative array abstraction

- **must** search for key and, if it is there, overwrite with new value
- otherwise, add new key, value at the beginning (as in stack)

23

- API
- basic implementations
- **iterators**
- Comparable keys
- challenges

24

## Iterators

Symbol tables should be **Iterable**

Q. What is **Iterable**?

A. Implements **iterator()**

Q. What is an **Iterator**?

A. Implements **hasNext()** and **next()**.

```
public interface Iterable<Item>
{
    Iterator<Item> iterator();
}
```

```
java.util.Iterator
public interface Iterator<Item>
{
    boolean hasNext();
    Item next();
    void remove(); // optional in Java
                    // use at your own risk
}
```

Q. Why should symbol tables be iterable?

A. Java language supports elegant client code for iterators

"foreach" statement

```
for (String s: st)
    StdOut.println(st.get(s));
```

equivalent code

```
Iterator<String> i = st.iterator();
while (i.hasNext())
{
    String s = i.next();
    StdOut.println(st.get(s));
}
```

25

## Iterable ST client: count frequencies of occurrence of input strings

Standard input: A file (of strings)

Standard output: All the distinct strings in the file with frequency

```
% more tiny.txt
it was the best of times
it was the worst of times
it was the age of wisdom
it was the age of foolishness

% java FrequencyCount < tiny.txt
2 age
1 best
1 foolishness
4 it
4 of
4 the
2 times
4 was
1 wisdom
1 worst
```

tiny example  
24 words  
10 distinct

real example  
137177 words  
9888 distinct

```
% more tale.txt
it was the best of times
it was the worst of times
it was the age of wisdom
it was the age of foolishness
it was the epoch of belief
it was the epoch of incredulity
it was the season of light
it was the season of darkness
it was the spring of hope
it was the winter of despair
we had everything before us
we had nothing before us
...
2941 a
% java FrequencyCount < tale.txt
1 aback
1 abandon
10 abandoned
1 abandoning
1 abandonment
1 abashed
1 abate
1 abated
5 abbaye
2 abed
1 abhorrence
1 abided
1 abiding
1 abilities
2 ability
1 abject
1 ablaze
17 able
1 abnegating
```

26

## Iterable ST client: count frequencies of occurrence of input strings

```
public class FrequencyCount
{
    public static void main(String[] args)
    {
        ST<String, Integer> st;
        st = new ST<String, Integer>();

        while (!StdIn.isEmpty())
        {
            String key = StdIn.readString(); // ← read a string

            if (!st.contains(key))
                st.put(key, 1); // ← insert
            else
                st.put(key, st.get(key) + 1); // ← increment
        }

        for (String s: st)
            StdOut.println(st.get(s) + " " + s); // ← print all strings
    }
}
```

Note: Only slightly more work required to build an **index** of all of the places where each key occurs in the text.

27

## Iterators for array, linked list ST implementations

```
import java.util.Iterator;
public class UnorderedST<Key, Value>
    implements Iterable<Key>
{
    ...

    public Iterator<Key> iterator()
    { return new ArrayIterator(); }

    private class ArrayIterator
        implements Iterator<Key>
    {
        private int i = 0;

        public boolean hasNext()
        { return i < N; }

        public void remove() { }

        public Key next()
        { return keys[i++]; }
    }
}
```

```
import java.util.Iterator;
public class LinkedListST<Key, Value>
    implements Iterable<Key>
{
    ...

    public Iterator<Key> iterator()
    { return new ListIterator(); }

    private class ListIterator
        implements Iterator<Key>
    {
        private Node current = first;

        public boolean hasNext()
        { return current != null; }

        public void remove() { }

        public Key next()
        {
            Key key = current.key;
            current = current.next;
            return key;
        }
    }
}
```

28

## Iterable ST client: A problem?

Use `UnorderedST` in `FrequencyCount`

```
% more tiny.txt
it was the best of times
it was the worst of times
it was the age of wisdom
it was the age of foolishness

% java FrequencyCount < tiny.txt
4 it
4 was
4 the
1 best
4 of
2 times
1 worst
2 age
1 wisdom
1 foolishness
```

Use `LinkedListST` in `FrequencyCount`

```
% more tiny.txt
it was the best of times
it was the worst of times
it was the age of wisdom
it was the age of foolishness

% java FrequencyCount < tiny.txt
1 foolishness
1 wisdom
2 age
1 worst
2 times
4 of
1 best
4 the
4 was
4 it
```

Clients who use `Comparable` keys might expect **ordered** iteration

- not a requirement for some clients
- not a problem if postprocessing, e.g. with `sort` or `grep`
- not in API

29

- ▶ API
- ▶ basic implementations
- ▶ iterators
- ▶ **Comparable keys**
- ▶ challenges

30

## Ordered array ST implementation

Assume that keys are `Comparable`

Maintain **parallel arrays** with keys and values that are **sorted by key**.

Instance variables

- `keys[i]` holds the *i*th smallest key
- `vals[i]` holds the value associated with the *i*th smallest key
- integer `N` holds the number of entries.

Note: no duplicate keys

`N = 6`  
↓

	0	1	2	3	4	5
<code>keys[]</code>	best	it	of	the	times	was
<code>vals[]</code>	1	2	1	1	1	2

Need to use standard array-doubling technique

Two reasons to consider using ordered arrays

- provides ordered iteration (for free)
- can use **binary search** to significantly speed up search

31

## Ordered array ST implementation (skeleton)

```
public class OrderedST
    <Key extends Comparable<Key>, Value>
    implements Iterable<Key>
{
    private Value[] vals;
    private Key[] keys;
    private int N = 0;
    public OrderedST(int maxN)
    {
        keys = (Key[]) new Object[maxN];
        vals = (Value[]) new Object[maxN];
    }

    public boolean isEmpty()
    { return N == 0; }

    public void put(Key key, Value val)
    // see next slides

    public Val get(Key key)
    // see next slides
}
```

← standard array iterator code omitted

← standard array doubling code omitted

32

## Ordered array ST implementation (search)

Keeping array in order enables **binary search** algorithm

```
public Value get(Key key)
{
    int i = bsearch(key);
    if (i == -1) return null;
    return vals[i];
}
```

```
private int bsearch(Key key)
{
    int lo = 0, hi = N-1;
    while (lo <= hi)
    {
        int m = lo + (hi - lo) / 2;
        int cmp = key.compareTo(keys[m]);
        if (cmp < 0) hi = m - 1;
        else if (cmp > 0) lo = m + 1;
        else return m;
    }
    return -1;
}
```

lo		m		hi				
0		4		8				
age	best	it	of	the	times	was	wisdom	worst
2	1	4	3	4	2	4	1	1

lo		m		hi	
0		3			
age	best	it	of		
2	1	4	3		

lo		m		hi	
		2		3	
		it	of		
		4	3		

lo		m		hi	
		3			
		of			
		3			

← get("of") returns 3

33

## Binary search analysis: Comparison count

Def.  $T(N)$  = number of comparisons to binary search in an ST of size  $N$

$$= \underset{\text{left or right half}}{T(N/2)} + \underset{\text{middle}}{1}$$

Binary search recurrence  $T(N) = T(N/2) + 1$   
for  $N > 1$ , with  $T(1) = 0$

- not quite right for odd  $N$
- same recurrence holds for many algorithms
- same number of comparisons for **any** input of size  $N$ .

Solution of binary search recurrence  $T(N) \sim \lg N$

- true for all  $N$
- easy to prove when  $N$  is a power of 2. ← can then use induction for general  $N$  (see COS 340)

34

## Binary search recurrence: Proof by telescoping

$$T(N) = T(N/2) + 1 \quad \text{for } N > 1, \text{ with } T(1) = 0 \quad (\text{assume that } N \text{ is a power of } 2)$$

Pf.  $T(N) = T(N/2) + 1$  given

$= T(N/4) + 1 + 1$  telescope (apply to first term)

$= T(N/8) + 1 + 1 + 1$  telescope again

...

$= T(N/N) + 1 + 1 + \dots + 1$  stop telescoping,  $T(1) = 0$

$= \lg N$

$$T(N) = \lg N$$

35

## Ordered array ST implementation (insert)

Binary search is little help for `put()`: still need to move larger keys

```
public Val put(Key key, Value val)
{
    int i = bsearch(key);
    if (i != -1)
    {
        vals[i] = val; return;
    }
    for (i = N; i > 0; i--)
    {
        if key.compareTo(keys[i-1] < 0) break;
        keys[i] = keys[i-1];
        vals[i] = vals[i-1];
    }
    vals[i] = val;
    keys[i] = key;
    N++;
}
```

← overwrite with new value if key in table

← move larger keys to make room if key not in table

age	best	it	of	the	times	was	wisdom	worst
2	1	4	4	4	2	4	1	1

age	best	foolish	it	of	the	times	was	wisdom	worst
2	1	1	4	4	4	2	4	1	1

← put("foolish")

36

## Ordered array ST implementation: an important special case

Test whether key is equal to or greater than largest key

```
public Val put(Key key, Value val)
{
    if (key.compareTo(keys[N-1]) == 0)
    { vals[N-1] = val; return; }

    if (key.compareTo(keys[N-1]) > 0)
    {
        vals[N] = val;
        keys[N] = key;
        N++;
        return;
    }
}
```

If either test succeeds, **constant-time** insert!

Method of choice for some clients:

- sort database by key
- insert N key-value pairs in order by key
- support searches that never use more than  $\lg N$  compares
- support occasional (expensive) inserts

37

## Ordered linked-list ST implementation

Binary search **depends on array indexing** for efficiency.

Jump to the middle of a linked list?

Advantages of keeping linked list in order for Comparable keys:

- support ordered iterator (for free)
- cuts search/insert time in half (on average) for random search/insert

[ code omitted ]

38

- ▶ API
- ▶ basic implementations
- ▶ iterators
- ▶ Comparable keys
- ▶ **challenges**

39

## Searching challenge 1A:

**Problem:** maintain symbol table of song names for an iPod

**Assumption A:** hundreds of songs

Which searching method to use?

- 1) unordered array
- 2) ordered linked list
- 3) ordered array with binary search
- 4) need better method, all too slow
- 5) doesn't matter much, all fast enough

40

#### Searching challenge 1B:

**Problem:** maintain symbol table of song names for an iPod

**Assumption B:** **thousands** of songs

Which searching method to use?

- 1) unordered array
- 2) ordered linked list
- 3) ordered array with binary search
- 4) need better method, all too slow
- 5) doesn't matter much, all fast enough

41

#### Searching challenge 2A:

**Problem:** IP lookups in a web monitoring device

**Assumption A:** **billions** of lookups, **millions** of distinct addresses

Which searching method to use?

- 1) unordered array
- 2) ordered linked list
- 3) ordered array with binary search
- 4) need better method, all too slow
- 5) doesn't matter much, all fast enough

42

#### Searching challenge 2B:

**Problem:** IP lookups in a web monitoring device

**Assumption B:** billions of lookups, **thousands** of distinct addresses

Which searching method to use?

- 1) unordered array
- 2) ordered linked list
- 3) ordered array with binary search
- 4) need better method, all too slow
- 5) doesn't matter much, all fast enough

43

#### Searching challenge 3:

**Problem:** Frequency counts in "Tale of Two Cities"

**Assumptions:** book has 135,000+ words  
about 10,000 distinct words

Which searching method to use?

- 1) unordered array
- 2) ordered linked list
- 3) ordered array with binary search
- 4) need better method, all too slow
- 5) doesn't matter much, all fast enough

44

#### Searching challenge 4:

**Problem:** Spell checking for a book

**Assumptions:** dictionary has 25,000 words  
book has 100,000+ words

Which searching method to use?

- 1) unordered array
- 2) ordered linked list
- 3) ordered array with binary search
- 4) need better method, all too slow
- 5) doesn't matter much, all fast enough

45

#### Searching challenge 5:

**Problem:** Sparse matrix-vector multiplication

**Assumptions:** matrix dimension is billions by billions  
average number of nonzero entries/row is ~10

Which searching method to use?

- 1) unordered array
- 2) ordered linked list
- 3) ordered array with binary search
- 4) need better method, all too slow
- 5) doesn't matter much, all fast enough

46

#### Summary and roadmap

- basic algorithmics
- no generics
- more code
- more analysis
- equal keys in ST (not associative arrays)

- iterators
- ST as associative array (all keys distinct)
- BST implementations
- applications

#### Symbol Tables

- API
- basic implementations
- iterators
- Comparable keys
- challenges

- distinguish algs by operations on keys
- ST as associative array (all keys distinct)
- important special case for binary search
- challenges

47

#### Elementary implementations: summary

implementation	worst case		average case		ordered iteration?	operations on keys
	search	insert	search	insert		
unordered array	N	N	N/2	N/2	no	<code>equals()</code>
ordered array	$\lg N$	N	$\lg N$	N/2	yes	<code>compareTo()</code>
unordered list	N	N	N/2	N	no	<code>equals()</code>
ordered list	N	N	N/2	N/2	yes	<code>compareTo()</code>

studying STs  
for the midterm?  
Start here.

Next challenge.

Efficient implementations of **search** and **insert** and **ordered iteration** for arbitrary sequences of operations.

(ordered array meets challenge if keys arrive approximately in order)
