#### File systems and databases: managing information

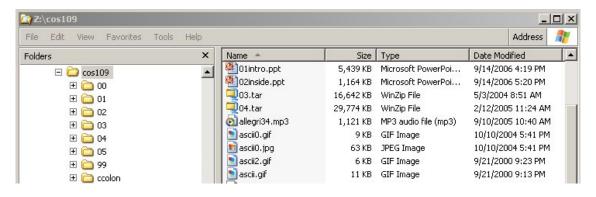

- · file: sequence of bytes stored on a computer
  - content is arbitrary; any structure is imposed by the creator of the file, not by the operating system
- file system: software that provides hierarchical storage and organization of files, usually on a single computer
  - part of the operating system
- · database: integrated collection of logically related records
  - data is organized and structured for efficient systematic access
- · database system: software that provides efficient access to information in a database
  - not usually part of an operating system

## File Systems: managing stored information

- logical structure: users and programs see a hierarchy of folders (or directories) and files
  - a folder contains references to folder and files
  - "root" folder ultimately leads to all others
  - a file is just a sequence of bytes
     contents determined and interpreted by programs, not the operating system
  - a folder is a special file that contains names of other folders & files
    plus other information like size, time of change, etc.
    contents are completely controlled by the operating system
- physical structure: disk drives operate in tracks, sectors, etc.
  - other storage devices have other physical properties
- · the operating system converts between these two views
  - does whatever is necessary to maintain the file/folder illusion
  - hides physical details so that programs don't depend on them
  - presents a uniform interface to disparate physical media
- the "file system" is the part of the operating system that does this conversion

#### Disks

- · a place to store information when the power is turned off
- usually based on magnetic surfaces, rotating machinery
- · logical / functional structure: folders (directories) and files
  - your information: papers, mail, music, web page, ...
  - programs and their data: Firefox, Word, iTunes, ...
  - operating system(s): Windows, MacOS, Unix/Linux, ...
  - bookkeeping info: where things are physically

#### How the file system converts logical to physical

- · disk is physically organized into sectors, or blocks of bytes
  - each sector is a fixed number of bytes, like 512 or 1024 or ...)
  - reading and writing always happens in sector-sized blocks
- · each file occupies an integral number of blocks
  - files never share a block
  - some space is wasted: a 1-byte file wastes all but 1 byte of the block
- · if a file is bigger than one block, it occupies several blocks
  - the blocks are not necessarily adjacent on the disk
- · need a way to keep track of the blocks that make up the file
- this is usually done by a separate "file allocation table" that lists the blocks that make up each file
  - this table is stored on disk too so it persists when machine is turned off
  - lots of ways to implement this

#### Converting logical to physical, continued

- every block is part of some file, or reserved by operating system, or unused
- · "file allocation table" keeps track of blocks
  - by chaining/linking them together
     first block of a file points to second, second points to third, etc.
     last block doesn't point to a successor (because it doesn't have one)
  - or (much more common) by some kind of table or array that keeps track of related blocks
- · also keeps track of unused blocks
  - disk starts out with most blocks unused ("free") some are reserved for file allocation table, etc.
  - as a file grows, blocks are removed from the unused list and attached to the list for the file:

to grow a file, remove a block from the list of unused blocks and add it to the blocks for the file

#### Converting logical to physical: directories

- · a directory / folder is a file
  - stored in the same file system
  - uses the same mechanisms
- · but it contains information about other files and directories
- · the directory entry for a file tells where to find the blocks
- · the directory entry also contains other info about the file
  - name (e.g., midterm.doc)
  - size in bytes, date/time of changes, access permissions
  - whether it's an ordinary file or a directory
- · the file system maintains the info in a directory
  - very important to keep directory info consistent
  - application programs can change it only indirectly / implicitly

#### Finding files; root directory

- · all files are ultimately accessible from the "root" directory/folder
  - e.g., C: on Windows, / on Unix and Mac
- to access the contents of a file named
   C:\Program Files\Adobe\Acrobat 8.0\Acrobat\acrobat.exe
  - read the blocks of C:, look for an entry with name "Program Files"
  - read the blocks of the Program Files directory, look for "Adobe"
  - read the blocks of Adobe, look for "Acrobat 8.0"
  - read the blocks of Acrobat 8.0, look for "Acrobat"
  - read the blocks of Acrobat, look for "acrobat.exe"
  - read the blocks of acrobat.exe
- · all but the last of these are directories/folders
- · the long name is often called the "path name"
  - since it describes a path through the file system hierarchy

# What happens when you say "Open"?

- search for file in sequence of directories
   as given by components of its name
  - report an error if any component can't be found
- · read blocks of the file as needed
  - using the location information in the file allocation table to find the blocks
  - store (some of) them in RAM

#### What happens when you say "Save"?

- · make sure there's enough space (enough unused blocks)
  - don't want to run out while copying from RAM to disk
- · create a temporary file with no bytes in it
- copy the bytes from RAM and/or existing file to temporary file:

```
while (there are still bytes to be copied) {
   get a free block from the unused list
   copy bytes to it until it's full or there are no more bytes to copy
   link it in to the temporary file
}
```

- · update the directory entry to point to the new file
- · move the previous blocks (of old version) to the unused list
  - or to recycle bin / trash

# What happens when you remove a file?

- · move the blocks of the file to the unused list
- · set the directory entry so it doesn't refer to any block
  - set it to zero, maybe
- · recycle bin
  - recycle bin is just another directory
  - removing a file just puts the name, location info, etc., in that directory instead
- · "emptying the trash" moves blocks into unused list
  - removes entry from Recycle / Trash directory
- · why "removing" a file isn't enough
  - usually only changes a directory entry
  - often recoverable by simple guesses about directory entry contents
  - file contents are often still there even if directory entry is cleared

## Network file systems

- software system for accessing remote files across networks
- user programs access files and folders as if they are on the local machine
- operating system converts these into requests to ship information to/from another machine across a network
- there has to be a program on the other end to respond to requests
- "mapping a network drive" or "mounting your H: drive" sets up the connections
- subsequent reads and writes go through the network instead of the local disk

#### Encrypted file systems

# TRUECRYPT

Free open-source disk encryption software for Windows 7/Vista/XP, Mac OS X, and Linux

#### Main Features:

- Creates a virtual encrypted disk within a file and mounts it as a real disk.
- Encrypts an entire partition or storage device such as USB flash drive or hard drive.
- Encrypts a partition or drive where Windows is installed (pre-boot authentication).
- Encryption is automatic, real-time (on-the-fly) and transparent.
- · Parallelization and pipelining allow data to be read and written as fast as if the drive was not encrypted.
- Provides plausible deniability, in case an adversary forces you to reveal the password:
   Hidden volume (steganography) and hidden operating system.
- · Encryption algorithms: AES-256, Serpent, and Twofish. Mode of operation: XTS.

Further information regarding features of the software may be found in the documentation.

What is new in TrueCrypt 6.3 (released October 21, 2009)

#### Databases and database systems

- · informally, database is a large collection of information
- · more formally, an organized collection of logically related records
- · data items have fixed set of attributes
  - name, address, phone number, gender, income, social security number, ...
- · each record has these attributes for a single person / instance

#### · database system supports

- very efficient search for records with specific properties all the women in 08540 with income > \$100K
- high volumes of traffic with concurrent access and update
   "ACID": atomic, consistent, isolated, durable

#### · major examples

- Oracle (owns Peoplesoft)
- MySQL (open source, now owned by Sun, in turn to be owned by Oracle...)
- SQLite (open source, in devices like iPhone)
