## Programming language components

- · statements: instructions that say what to do
  - compute values, make decisions, repeat sequences of operations
- · variables: places to hold data in memory while program is running
  - numbers, text, ...
- · syntax: grammar rules for defining legal statements
  - what's grammatically legal? how are things built up from smaller things?
- · semantics: what things mean
  - what do they compute?
- most languages are higher-level and more expressive than the assembly language for the toy machine
  - statements are much richer, more varied, more expressive
  - variables are much richer, more varied
  - grammar rules are more complicated
  - semantics are more complicated
- · but it's basically the same idea

#### Why study / use Javascript?

- · all browsers process Javascript
  - many web services rely on Javascript in browser
  - can use it in your own web pages
  - can understand what other web pages are doing (and steal from them)
- · easy to start with
- easy to do useful things with it
- · programming ideas carry over into other languages
- · Javascript has limitations:
  - no use outside of web pages
  - many irregularities and surprising behaviors
  - no browser matches ostensible standards exactly
  - doesn't illustrate much about how big programs are built

#### Javascript components

- Javascript language
  - statements that tell the computer what to do get user input, display output, set values, do arithmetic, test conditions, repeat groups of statements, ...
- · libraries, built-in functions
  - pre-fabricated pieces that you don't have to create yourself alert, prompt, math functions, text manipulation, ...
- access to browser and web pages
  - buttons, text areas, images, page contents, ...
- · you are not expected to remember syntax or other details
- you are not expected to write code in exams (though a bit in problem sets and labs)
- · you are expected to understand the ideas
  - how programming and programs work
  - figure out what a tiny program does or why it's broken

#### Basic example #1: join 2 names (name2.html)

- Javascript code appears in HTML file between <script> tags
   <script language=javascript> . . . </script>
- · shows variables, dialog boxes, an operator

```
<html>
<body>
<P> name2.html: joins 2 names
<script>
    var firstname, secondname, result;
    firstname = prompt("Enter first name");
    secondname = prompt("Enter last name");
    result = firstname + secondname; // + means "join" here alert("hello, " + result); // and here
</script>
```

#### Basic example #2: add 2 numbers (add2.html)

· dialog boxes, variables, arithmetic, conversion

```
<html>
<body>
<P> add2.html: adds 2 numbers
<script>
    var num1, num2, sum;
    num1 = prompt("Enter first number");
    num2 = prompt("Enter second number");
    sum = parseInt(num1) + parseInt(num2); // "+" means "add"
    alert(sum);
</script>

parseInt(...) converts a sequence of characters into its integer value
    there's also a parseFloat(...) for floating point numbers
```

# Adding up lots of numbers: addup.html

- · variables, operators, expressions, assignment statements
- while loop, relational operator (!= "not equal to")

```
<html>
<body>
<script>
    var sum = 0;
    var num;
    num = prompt("Enter new value, or 0 to end");
    while (num != 0) {
        sum = sum + parseInt(num);
        num = prompt("Enter new value, or 0 to end");
    }
    alert("Sum = " + sum);
</script>
```

## Find the largest number: max.html

- · needs an If to test whether new number is bigger
- needs another relational operator
- · needs parseInt or parseFloat to treat input as a number

```
var max = 0;
var num;
num = prompt("Enter new value, or 0 to end");
while (num != 0) {
   if (parseFloat(num) > max)
       max = num;
   num = prompt("Enter new value, or 0 to end");
}
document.write("<P> Max = " + max);
```

## Variables, constants, expressions, operators

- · a variable is a place in memory that holds a value
  - has a name that the programmer gave it, like sum or Area or n
  - in Javascript, can hold any of multiple types, most often numbers like 1 or 3.14, or

sequences of characters like "Hello" or "Enter new value"

- always has a value
- has to be set to some value initially before it can be used
- its value will generally change as the program runs
- ultimately corresponds to a location in memory
- but it's easier to think of it just as a name for information
- · a constant is an unchanging literal value like 3 or "hello"
- an expression uses operators, variables and constants to compute a value

```
3.14 * rad * rad
```

operators include + - \* /

# Computing area: area.html

```
var rad, area;
rad = prompt("Enter radius");
while (rad != null) {
    area = 3.14 * rad * rad;
    document.write("<P> radius = " + rad + ", area = " + area);
    rad = prompt("Enter radius");
}
```

- · how to terminate the loop
  - 0 is a valid data value
  - prompt() returns null for Cancel and "" for OK without typing any text
- · string concatenation to build up output line
- · there is no exponentiation operator so we use multiplication

## Types, declarations, conversions

- · variables have to be declared in a var statement
- · each variable holds information of a specific type
  - really means that bits are to be interpreted as info of that type
  - internally, 3 and 3.00 and "3.00" are represented differently
- Javascript usually infers types from context, does conversions automatically
  - "Sum = " + sum
- · sometimes we have to be explicit:
  - parseInt(...) if can't tell from context that string is meant as an integer
  - parseFloat(...) if it could have a fractional part

## Making decisions and repeating statements

· if-else statement makes decisions

```
- the Javascript version of decisions written with ifzero, ifpos, ...
    if (condition is true) {
        do this group of statements
    } else {
        do this group of statements instead
    }
· while statement repeats groups of statements
    - a Javascript version of loops written with ifzero and goto
    while (condition is true) {
         do this group of statements
    }
```

# if-else examples (sign.html)

· can include else-if sections for a series of decisions:

```
var num = prompt("Enter number");
while (num != null) {
    num = parseInt(num);
    if (num > 0) {
        alert(num + " is positive");
    } else if (num < 0) {</pre>
        alert(num + " is negative");
    } else {
        alert(num + " is zero");
    num = prompt("Enter number");
}
```

## "while loop" examples

· counting or "indexed" loop:

```
i = 1;
while (i <= 10) {
    // do something (maybe using the current value of i)
    i = i + 1;
}</pre>
```

· "nested" loops (while.html):

#### **Functions**

- · a function is a group of statements that does some computation
  - the statements are collected into one place and given a name
  - other parts of the program can "call" the function
     that is, use it as a part of whatever they are doing
  - can give it values to use in its computation (arguments or parameters)
  - computes a value that can be used in expressions
  - the value need not be used
- · Javascript provides some useful built-in functions
  - e.g., prompt, alert, ...
- · you can write your own functions

#### Function examples

· syntax

```
function name (list of "arguments") {
    the statements of the function
}
```

function definition:

```
function area(r) {
   return 3.14 * r * r;
}
```

· using ("calling") the function:

```
rad = prompt("Enter radius");
alert("radius = " + rad + ", area = " + area(rad));
alert("area of CD =" + area(2.3) - area(0.8));
```

## Why use functions?

- · if a computation appears several times in one program
  - a function collects it into one place
- · breaks a big job into smaller, manageable pieces
  - that are separate from each other
- · defines an interface
  - implementation details can be changed as long as it still does the same job
  - different implementations can interoperate
- · multiple people can work on the program
- · a way to use code written by others long ago and far away
  - most of Javascript's library of useful stuff is accessed through functions
- · a good library encourages use of the language

## Summary: elements of (most) programming languages

- · constants: literal values like 1, 3.14, "Error!"
- variables: places to store data and results during computing
- · declarations: specify name (and type) of variables, etc.
- expressions: operations on variables and constants to produce new values
- · assignment: store a new value in a variable
- statements: assignment, input/output, loop, conditional, call
- · conditionals: compare and branch; if-else
- · loops: repeat statements while a condition is true
- functions: package a group of statements so they can be called/ used from other places in a program
- · libraries: functions already written for you

#### How Javascript works

- recall the process for Fortran, C, etc.:
   compiler -> assembler -> machine instructions
- · Javascript is analogous, but differs significantly in details
- when the browser sees Javascript in a web page (<script> tags)
  - passes the Javascript program to a Javascript compiler
- Javascript compiler
  - checks for errors
  - compiles the program into instructions for something like the toy machine, but richer, more complicated, higher level
  - runs a simulator program (like the toy) that interprets these instructions
- simulator is often called an "interpreter" or a "virtual machine"
  - probably written in C or C++ but could be written in anything
- · browser and simulator interact
  - when an event like click happens, browser tells Javascript ("onClick")
  - Javascript tells browser to do things (e.g., pop up dialog box for alert)

## The process of programming

- · what we saw with Javascript or Toy is like reality, but very small
- · figure out what to do
  - start with a broad specification
  - break into smaller pieces that will work together
  - spell out precise computational steps in a programming language
- build on a foundation (rarely start from scratch)
  - a programming language that's suitable for expressing the steps
  - components that others have written for you functions from libraries, major components, ...
  - which in turn rest on others, often for several layers
  - runs on software (the operating system) that manages the machine
- · it rarely works the first time
  - test to be sure it works, debug if it doesn't
  - evolve as get a better idea of what to do, or as requirements change

## Real-world programming

- · the same thing, but on a grand scale
  - programs may be millions of lines of code
     typical productivity: 1-10K lines/year/programmer
  - thousands of people working on them
  - lifetimes measured in years or even decades
- · big programs need teams, management, coordination, meetings, ...
- schedules and deadlines
- · constraints on how fast the program must run, how much memory it can use
- external criteria for reliability, safety, security, interoperability with other systems, ...
- · maintenance of old ("legacy") programs is hard
  - programs must evolve to meet changing environments and requirements
  - machines and tools and languages become obsolete
  - expertise disappears
