3. Conditionals and loops

3. Conditionals & Loops

- Conditionals: the if statement
- Loops: the while statement
- An alternative: the for loop
- Nesting
- Debugging

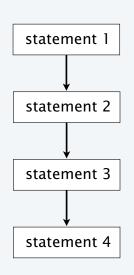

Context: basic building blocks for programming

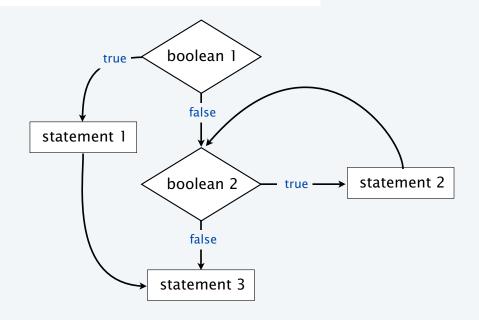

Conditionals and Loops

Control flow

- The sequence of statements that are actually executed in a program.
- Conditionals and loops enable us to choreograph control flow.

straight-line control flow [previous lecture]

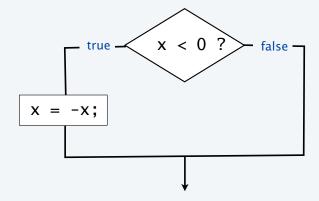

control flow with conditionals and a loop [this lecture]

The if statement

Execute certain statements depending on the values of certain variables.

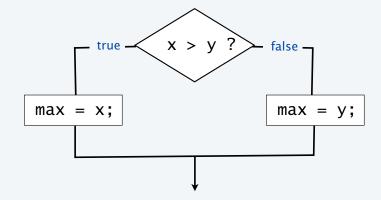

- Evaluate a boolean expression.
- If true, execute a statement.
- The else option: If false, execute a different statement.

Example: if (x < 0) x = -x;

Computes the absolute value of x

Computes the maximum of x and y

Example of if statement use: simulate a coin flip

```
public class Flip
{
    public static void main(String[] args)
    {
       if (Math.random() < 0.5)
            System.out.println("Heads");
       else System.out.println("Tails");
    }
}</pre>
```

% java Flip Heads

% java Flip Heads

% java Flip Tails

% java Flip Heads

Example of if statement use: 2-sort

Q. What does this program do?

```
% java TwoSort 1234 99
99
1234

% java TwoSort 99 1234
99
1234
```

A. Reads two integers from the command line, then prints them out in numerical order.

Pop quiz on if statements

Q. Add code to this program that puts a, b, and c in numerical order.

```
public class ThreeSort
{
   public static void main(String[] args)
   {
      int a = Integer.parseInt(args[0]);
      int b = Integer.parseInt(args[1]);
      int c = Integer.parseInt(args[2]);

      StdOut.println(a);
      StdOut.println(b);
      StdOut.println(c);
   }
}
```

```
% java ThreeSort 1234 99 1
1
99
1234

% java ThreeSort 99 1 1234
1
99
1234
```

Example of if statement use: error checks

```
% java IntOps 5 2
5 + 2 = 7
5 * 2 = 10
5 / 2 = 2
5 % 2 = 1

% java IntOps 5 0
5 + 0 = 5
5 * 0 = 0
Division by zero
Division by zero
```

Good programming practice. Use conditionals to check for and avoid runtime errors.

3. Conditionals & Loops

- Conditionals: the if statement
- Loops: the while statement
- An alternative: the for loop
- Nesting
- Debugging

The while loop

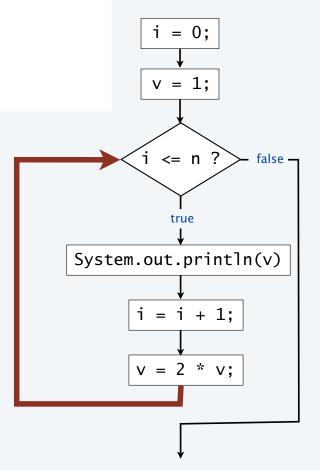

Execute certain statements repeatedly until certain conditions are met.

- Evaluate a boolean expression.
- If true, execute a sequence of statements.
- Repeat.

```
Example:
    int i = 0;
    int v = 1;
    while (i <= n)
    {
        System.out.println(v);
        i = i + 1;
        v = 2 * v;
    }
}</pre>
```

Prints the powers of two from 2^0 to 2^n .

[stay tuned for a trace]

Example of while loop use: print powers of two

```
public class PowersOfTwo
   public static void main(String[] args)
      int n = Integer.parseInt(args[0]);
      int i = 0;
      int v = 1;
      while (i <= n)
         System.out.println(v);
         i = i + 1;
         v = 2 * v;
```

```
i
      V
            i <= n
0
      1
             true
      2
1
             true
      4
             true
3
      8
             true
4
     16
             true
     32
5
             true
6
     64
             true
            false
7
     128
```

```
% java PowersOfTwo 6
1
2
4
8
16
32
64
```

Prints the powers of two from 2^0 to 2^n .

Pop quiz on while loops

Q. Anything wrong with the following code?

```
public class PQwhile
{
   public static void main(String[] args)
   {
      int n = Integer.parseInt(args[0]);
      int i = 0;
      int v = 1;
      while (i <= n)
            System.out.println(v);
      i = i + 1;
      v = 2 * v;
   }
}</pre>
```

Example of while loop use: implement Math.sqrt()

Goal. Implement square root function.

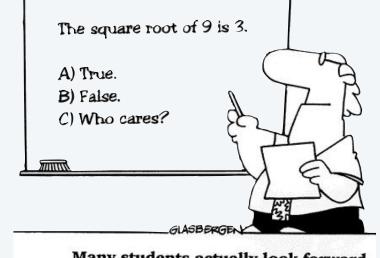

% java Sqrt 60481729
7777.0
% java Sqrt 2
1.4142136

Newton-Raphson method to compute \sqrt{c}

- Initialize $t_0 = c$. if t = c/t then $t^2 = c$
- Repeat until $t_i = c/t_i$ (up to desired precision): Set t_{i+1} to be the average of t_i and c / t_i .

i	ti	$2/t_i$	average
0	2.0	1.0	1.5
1	1.5	1.3333333	1.4166667
2	1.4166667	1.4117647	1.4142157
3	1.4142157	1.4142114	1.4142136
4	1.4142136	1.4142136	

computing the square root of 2 to seven places

Many students actually look forward to Mr. Atwadder's math tests.

Example of while loop use: implement Math.sqrt()

Newton-Raphson method to compute \sqrt{c}

- Initialize $t_0 = c$.
- Repeat until $t_i = c/t_i$ (up to desired precision): Set t_{i+1} to be the average of t_i and c/t_i .

```
public class Sqrt
{
    public static void main(String[] args)
    {
        double EPS = 1E-15; 	— error tolerance (15 places)
        double c = Double.parseDouble(args[0]);
        double t = c;
        while (Math.abs(t - c/t) > t*EPS)
        { t = (c/t + t) / 2.0; }
        System.out.println(t);
    }
}
```

Isaac Newton 1642-1727

Scientists studied computation well before the onset of the computer.

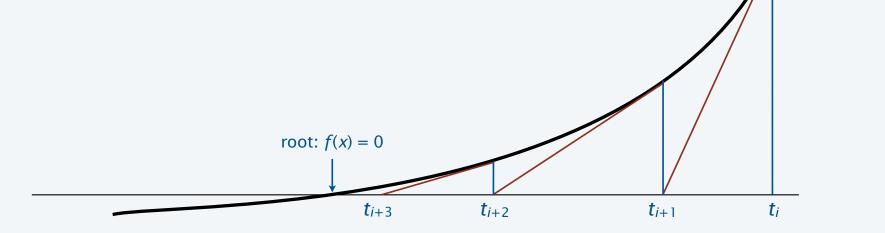

```
% java Sqrt 60481729
7777.0
```

% java Sqrt 2.0 1.414213562373095

Newton-Raphson method

Explanation (some math omitted)

- Goal: find root of function f(x). \leftarrow use $f(x) = x^2 c$ for \sqrt{c}
- Start with estimate t₀.
- Draw line tangent to curve at $x = t_i$.
- Set t_{i+1} to be x-coordinate where line hits x-axis.
- Repeat until desired precision.

3. Conditionals & Loops

- Conditionals: the if statement
- Loops: the while statement
- An alternative: the for loop
- Nesting
- Debugging

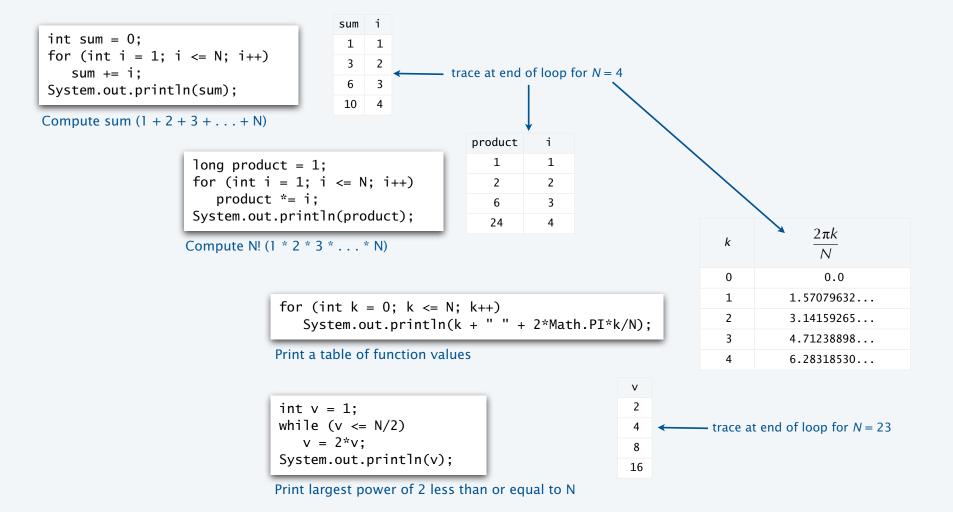

The for loop

An alternative repetition structure. Why? Can provide code that is more compact and understandable.

- Evaluate an initialization statement.
- Evaluate a boolean expression.
- If true, execute a sequence of statements, then execute an *increment statement*.
- Repeat.

```
Example:
                                  initialization statement
                                                       Every for loop has an equivalent while loop:
   int v = 1;
                                                           int v = 1;
   for ((int i = 0))(i <= n)(i++)
                                                           int i = 0;
                                   _boolean expression
                                                           while ((i \le n;))
                                 " " + v );
      System.out.println( i +
                                                              System.out.println( i + " " + v );
      v = 2*v:
                                      increment statement
                                                              v = 2*v;
    Prints the powers of two from 2^0 to 2^n
```

Examples of for loop use

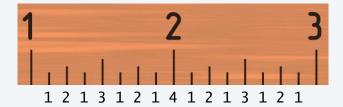

Example of for loop use: subdivisions of a ruler

Create subdivisions of a ruler to 1/N inches.

- Initialize ruler to one space.
- For each value i from 1 to N: sandwich i between two copies of ruler.

```
public class Ruler
{
   public static void main(String[] args)
   {
      int N = Integer.parseInt(args[0]);
      String ruler = " ";
      for (int i = 1; i <= N; i++)
        ruler = ruler + i + ruler;
      System.out.println(ruler);
   }
}</pre>
```

Note: Small progam can produce huge amount of output.

i	ruler
1	"1"
2	"121"
3	"1213121"
4	"121312141213121"

End-of-loop trace

```
java Ruler 4
1 2 1 3 1 2 1 4 1 2 1 3 1 2 1
```

% java Ruler 100
Exception in thread "main"
java.lang.OutOfMemoryError

# Include (Stato.h)

int count;

for (count = 1; count <= 500; count++)

printf ("I will not throw paper dirplanes in class.");

return 0;

Pop quiz on for loops (easy if you read exercise 1.3.13)

Q. What does the following program print?

```
public class PQfor
{
    public static void main(String[] args)
    {
        int f = 0, g = 1;
        for (int i = 0; i <= 10; i++)
        {
            System.out.println(f);
            f = f + g;
            g = f - g;
        }
    }
}</pre>
```

3. Conditionals & Loops

- Conditionals: the if statement
- Loops: the while statement
- An alternative: the for loop
- Nesting
- Debugging

Nesting conditionals and loops

Nesting

- Any "statement" within a conditional or loop may itself be a conditional or a loop statement.
- Enables complex control flows.
- Adds to challenge of debugging.

if-else statement within a while loop within a for loop

[Stay tuned for an explanation of this code.]

Example of nesting conditionals: Tax rate calculation

Goal. Given income, calculate proper tax rate.

income	rate
0 - \$47,450	22%
\$47,450 - \$114,649	25%
\$114,650 - \$174,699	28%
\$174,700 - \$311,949	33%
\$311,950 +	35%

```
if (income < 47450) rate = 0.22;
else
                                                                       if statement
                                                                       within an if statement
      if (income < 114650) rate = 0.25;
      else
                                                                       if statement
             if (income < 174700) rate = 0.28;
                                                                       within an if statement
             else
                                                                       within an if statement
                    if (income < 311950) rate = 0.33;
                                                                       if statement
                                           rate = 0.35;
                    else
                                                                       within an if statement
                                                                       within an if statement
                                                                       within an if statement
```

Pop quiz on nested if statements

Q. Anything wrong with the following code?

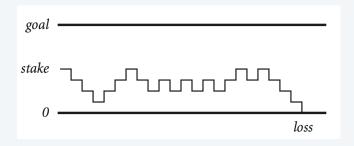

```
public class PQif
{
   public static void main(String[] args)
   {
      double income = Double.parseDouble(args[0]);
      double rate = 0.35;
      if (income < 47450) rate = 0.22;
      if (income < 114650) rate = 0.25;

Gambler's ruin problem

A gambler starts with \$stake and places \$1 fair bets.

- Outcome 1 (loss): Gambler goes broke with \$0.
- Outcome 2 (win): Gambler reaches \$goal.

- Q. What are the chances of winning?
- Q. How many bets until win or loss?

One approach: Monte Carlo simulation.

- Use a simulated coin flip.
- Repeat and compute statistics.

Example of nesting conditionals and loops: Simulate gamber's ruin

Gambler's ruin simulation

- Get command-line parms.
- Run all the experiments.
 - Run one experiment.
 - · Make one bet.
 - If goal met, count the win.
- Print #wins and # trials.

```
public class Gambler
    public static void main(String[] args)
      int stake = Integer.parseInt(args[0]);
                  = Integer.parseInt(args[1]);
      int goal
      int trials = Integer.parseInt(args[2]);
      int wins = 0;
      for (int i = 0; i < trials; i++)
                                                          for loop
         int t = stake;
                                                          while loop
          while (t > 0 \&\& t < qoal)
                                                          within a for loop
             if (Math.random() < 0.5) t++;</pre>
                                                           if statement
             else
                                                          within a while loop
                                                          within a for loop
          if (t == goal) wins++;
      StdOut.println(wins + " wins of " + trials);
}
                                            % java Gambler
                                                              25 1000
                                            203 wins of 1000
```

Digression: simulation and analysis

Facts (known via mathematical analysis for centuries)

- Probability of winning = stake ÷ goal.
- Expected number of bets = stake \times desired gain.

Early scientists were fascinated by the study of games of chance.

stake goal trials

Christiaan Huygens 1629-1695

Example

- 20% chance of turning \$500 into \$2500.
- Expect to make 1 million \$1 bets.

500/2500 = 20%

500*(2500 - 500) = 1,000,000

uses about 1 billion coin flips

- % java Gambler 25 1000 191 wins of 1000
- % java Gambler 25 1000 203 wins of 1000
- % java Gambler 500 2500 1000 197 wins of 1000

Remarks

- Computer simulation can help validate mathematical analysis.
- For this problem, mathematical analysis is simpler (if you know the math).
- For more complicated variants, computer simulation may be the best plan of attack.

3. Conditionals & Loops

- Conditionals: the if statement
- Loops: the while statement
- An alternative: the for loop
- Nesting
- Debugging

Debugging

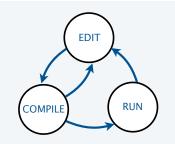

is 99% of program development in any programming language, even for experts.

Bug: A mistake in a program.

Debugging: The process of eliminating bugs.

You will make many mistakes as you write programs. It's normal.

"As soon as we started programming, we found out to our surprise that it wasn't as easy to get programs right as we had thought. I can remember the exact instant when I realized that a large part of my life from then on was going to be spent in finding mistakes in my own programs."

– Maurice Wilkes

Impossible ideal: "Please compile, execute, and debug my progam." — Why is this impossible? Stay tuned.

Bottom line: Programming is primarily a process of finding and fixing mistakes.

Debugging

is challenging because conditionals and loops dramatically increase the number of possible outcomes.

program structure	no loops	N conditionals	1 <i>loop</i>
number of possible execution sequences	1	2 <i>N</i>	no limit

Most programs contain numerous conditionals and loops, with nesting.

Good news. Conditionals and loops provide structure that helps us understand our programs.

Old and low-level languages have a *goto* statement that provides arbitrary structure. Eliminating *goto*s was controversial until Edsgar Dijkstra published the famous note "*Goto considered harmful*" in 1968.

"The quality of programmers is a decreasing function of the number of goto statements in the programs they produce."

– Edsgar Dijkstra

Debugging a program: a running example

Problem: Factor a large integer N.

Application: Cryptography.

Suprising fact: Security of internet commerce depends on difficulty of factoring large integers.

Method

- Consider each integer i less than N
- While i divides N evenly
 Print i (it is a factor of N).
 Replace N with N/i.

Rationale:

- 1. Any factor of N/i is a factor of N.
- 2. *i* may be a factor of *N/i*.

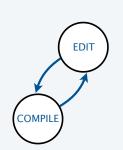

```
3,757,208 = 2 \times 2 \times 2 \times 7 \times 13 \times 13 \times 397
98 = 2 \times 7 \times 7
17 = 17
11,111,111,111,111 = 2,071,723 \times 5,363,222,357
```

```
public class Factors
{
   public static void main(String[] args)
   {
     long N = Long.parseLong(args[0])
     for (i = 0; i < N; i++)
      {
        while (N % i == 0)
            System.out.print(i + " ")
            N = N / i
        }
   }
}
This program has bugs!</pre>

Debugging a program: syntax errors

Is your program a legal Java program?

- Java compiler can help you find out.
- Use javac to find the first error.
- ⊶ Repeat.
- Result: An executable Factors.class file

Trying to tell a computer what to do

```
% javac Factors.java
%
```

need terminating semicolons

Debugging a program: runtime and semantic errors

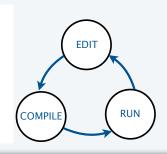

Does your legal Java program do what you want it to do?

- You need to run it to find out.
 - Use java runtime to find the first error.
 - Fix and repeat.

```
% java Factors 98
2 7 7%
```

```
98 = 2 \times 7 \times 7
```

Debugging a program: testing

Does your legal Java program *always* do what you want it to do?

- You need to test on many types of inputs it to find out.
- Add trace code to find the first error.
 - Fix the error.
 - Repeat.

```
% java Factors 98
2 7 7% ← need newline

% java Factors 5
← ???? no output

% java Factors 6
2 ← ??? where's the 3?
```

```
% javac Factors.java
% java Factors 5
TRACE 2 5
TRACE 3 5
TRACE 4 5
% java Factors 6

Debugging a program: performance

Is your working Java program fast enough to solve your problem?

- You need to test it on increasing problem sizes to find out.
- May need to change the algorithm to fix it.
- Repeat.

Method

might work,

but way too slow

change the *algorithm*: no need to check when $i \cdot i > N$ since all smaller factors already checked

- Consider each integer $(i \le N/i)$
- While i divides N evenly
 print i (it is a factor of N)

Debugging a program: performance analysis

Q. How large an integer can I factor?

% java Factors 920111116975555703 9201111169755555703

digits in largest factor	i < N	i <= N/i
3	instant	instant
6	instant	instant
9	77 seconds instant	
12	21 hours [†]	instant
15	2.4 years†	2.7 seconds
18	2.4 millenia [†]	92 seconds

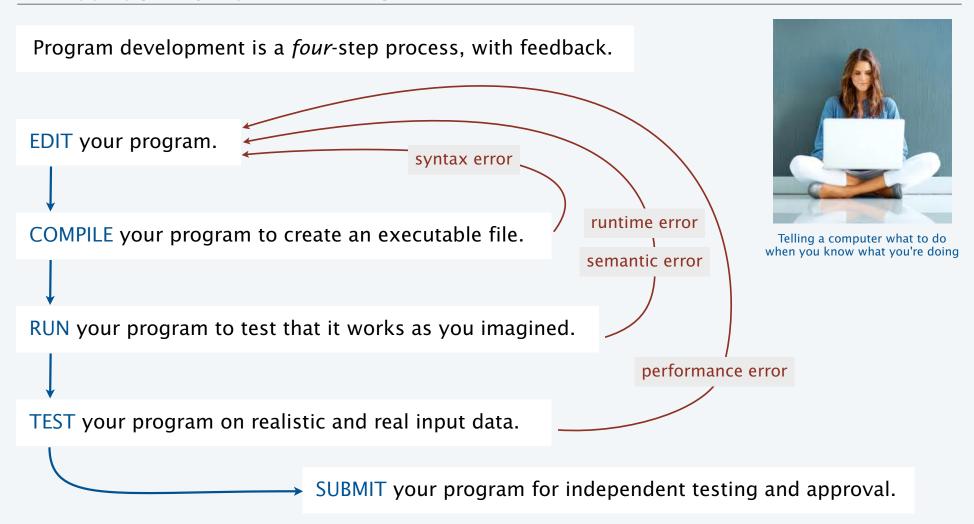

† estimated, using analytic number theory

Lesson. Performance matters!

experts are still trying to develop better algorithms for this problem

Note. Internet commerce is still secure: it depends on the difficulty of factoring 200-digit integers.
