

Point Set Alignment

Thomas Funkhouser

COS 526, Fall 2016

Motivation

Point sets to be aligned

➤ **Range scans**

- Image features
- Molecules
- etc.

Motivation

Point sets to be aligned

- Range scans
- Image features
- Molecules
- etc.

Motivation

Point sets to be aligned

- Range scans
- Image features
- Molecules
- etc.

Goal

Given two partially overlapping point sets,
compute the transformation that merges the two

Partially Overlapping Scans

Aligned Scans

General Approach

1. Find feature points

Partially Overlapping Scans

General Approach

1. Find feature points
2. Establish correspondences

Partially Overlapping Scans

General Approach

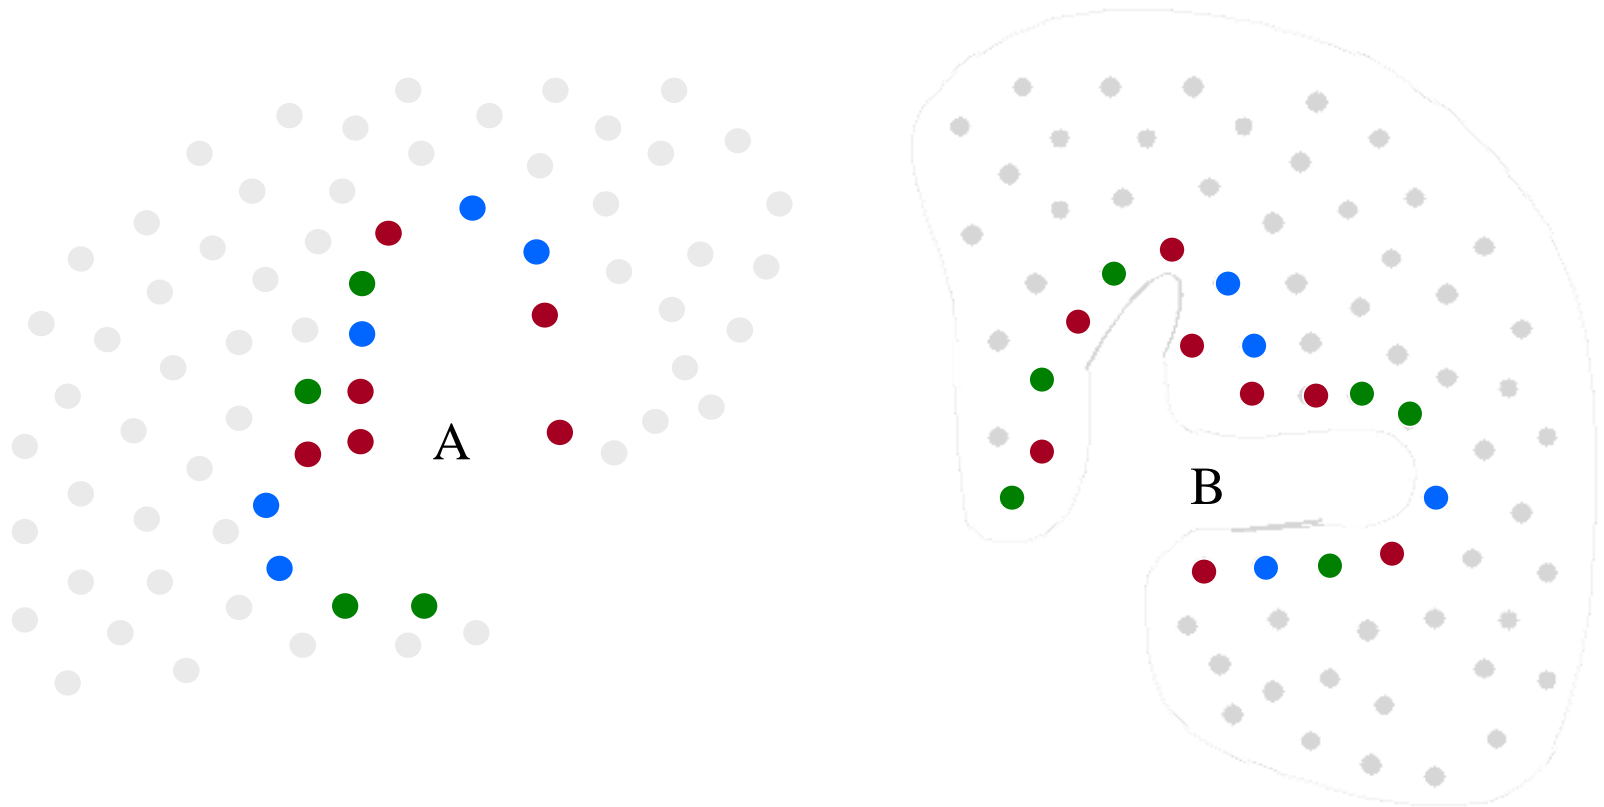

1. Find feature points
2. Establish correspondences
3. Compute the aligning transformation

Problem

Most problems require aligning a subset of features

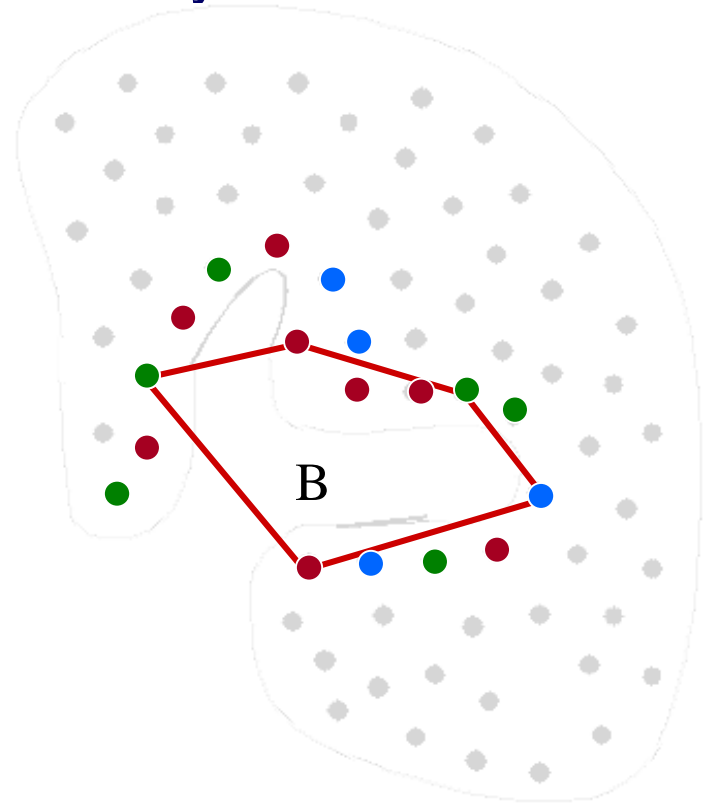

Problem

Most problems require aligning a subset of features

- Find the maximal subsets of points that align with error E
- Find the minimum misalignment for any subset of a size S

Observation I

Calculating the aligning transformation is usually easy if correspondences are known (proposed)

$$RMSD(A, B) = \sqrt{\sum_{i=1}^N (A_i - B_i)^2}$$

Observation II

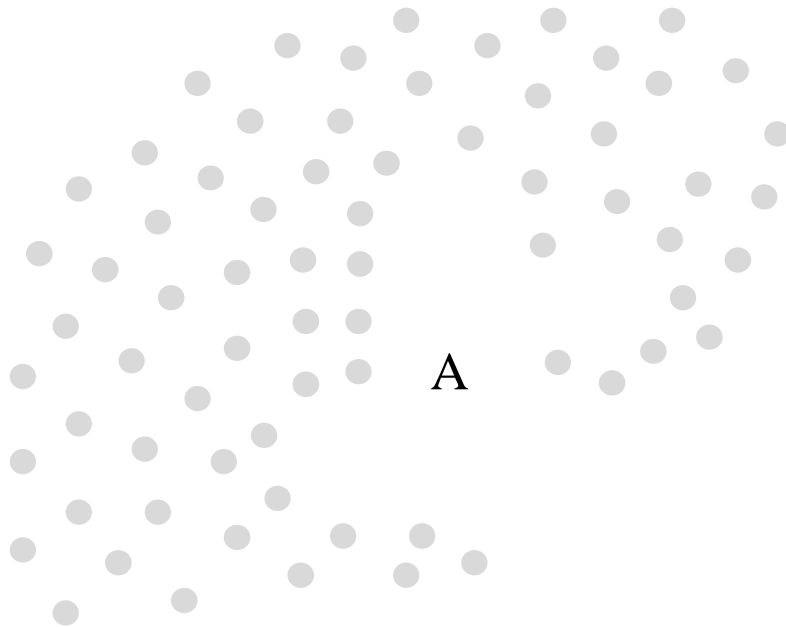

Calculating the correspondences is usually easy if the aligning transformation is known (proposed)

Challenge

The challenge is to discover the correspondences and aligning transformation together

Outline

Introduction

Point set matching

- Brute force search
- RANSAC
- Geometric hashing
- Association graphs
- Generalized Hough transform
- Iterative closest point

Methods used for RGB-D scanning

Discussion

Brute Force Search

Simple method:

- Try all possible sets of point correspondences
- Score the alignment for each one

Problem:

- $O(n^m)$ possible sets of m correspondences among n points

Brute Force Search

Simple method:

- Try all possible sets of point correspondences
- Score the alignment for each one

Problem:

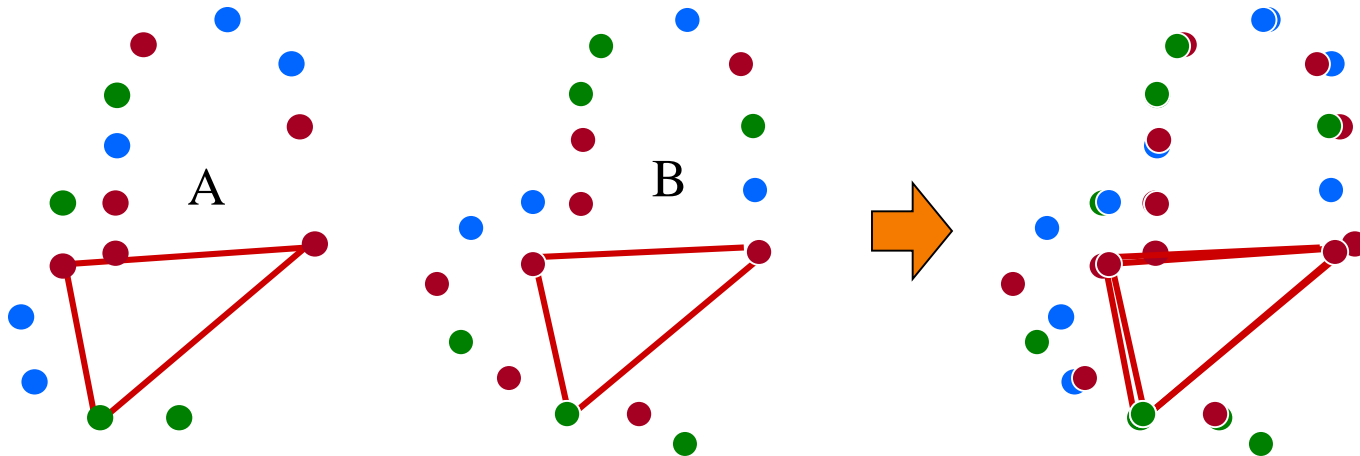

- $O(n^m)$ possible sets of m correspondences among n points

Brute Force Search

Simple method:

- Try all possible sets of point correspondences
- Score the alignment for each one (e.g., RMSD)

Problem:

- $O(n^m)$ possible sets of m correspondences among n points

All points aligned
RMSD = 0.2

Outline

Introduction

Point set matching

- Brute force search
- **RANSAC**
- Geometric hashing
- Association graphs
- Generalized Hough transform
- Iterative closest point

Methods used for RGB-D scanning

Discussion

RANSAC

Randomly sample set of possible correspondences

- Randomly generate a small set of point correspondences
- Compute the aligning transformation for correspondences
Score how well other points align after that transformation
- Remember the best transformation

RANSAC

RANSAC loop:

1. Select k matches (at random)
2. Compute transformation T aligning those matches
3. Find *inlier matches* where $d(p_i', T p_i) < \varepsilon$
4. Re-compute T to align on all of its inliers
5. Re-find *inlier matches* where $d(p_i', T p_i) < \varepsilon$
6. $T^* = T$ if has T largest set of inliers seen so far

Warp image by T^*

Composite images

RANSAC for Image Mosaics

RANSAC loop:

1. Select four matches (at random)
2. Compute homography H aligning those matches
3. Find *inlier matches* where $d(p_i', \mathbf{H}p_i) < \varepsilon$
4. Re-compute H to align on all of its inliers (least squares)
5. Re-find *inlier matches* where $d(p_i', \mathbf{H}p_i) < \varepsilon$
6. $H^* = H$ if has H largest set of inliers seen so far

Warp image by H^* and composite images

RANSAC for Image Mosaics

RANSAC loop:

1. **Select four matches (at random)**
2. Compute homography H aligning those matches
3. Find *inlier matches* where $d(p_i', H p_i) < \varepsilon$
4. Re-compute H to align on all of its inliers (least squares)
5. Re-find *inlier matches* where $d(p_i', H p_i) < \varepsilon$
6. $H^* = H$ if has H largest set of inliers seen so far

Warp image by H^* and composite images

RANSAC for Image Mosaics

RANSAC loop:

1. Select four matches (at random)
2. Compute homography H aligning those matches
3. Find *inlier matches* where $d(p_i', H p_i) < \varepsilon$
4. Re-compute H to align on all of its inliers (least squares)
5. Re-find *inlier matches* where $d(p_i', H p_i) < \varepsilon$
6. $H^* = H$ if has H largest set of inliers seen so far

all point sets

Store (point set, ref. frame, properties, point)
for every transformed point in hash table

Hash Table

Geometric Hashing

Query processing

Geometric Hashing

Preprocessing complexity

- $O(n^4)$ for n points per binding site
 - $O(n^3)$ possible triples * $O(n)$ transformations per triple

Query complexity

- $O(m)$ * binsize for m points in query binding site
 - 1 triple * $O(m)$ transformations per triple *
binsize hash processing per transformation

Discussion

Association Graphs

Association Graphs

Represent both points sets as complete graphs (G1 and G2).
(edges connect all pairs of vertices within each point set)

Association Graphs

G1

Association Graph

G2

Create vertices in the association graph for all compatible pairs of vertices in the original graphs. This can lead to a large number of vertices.

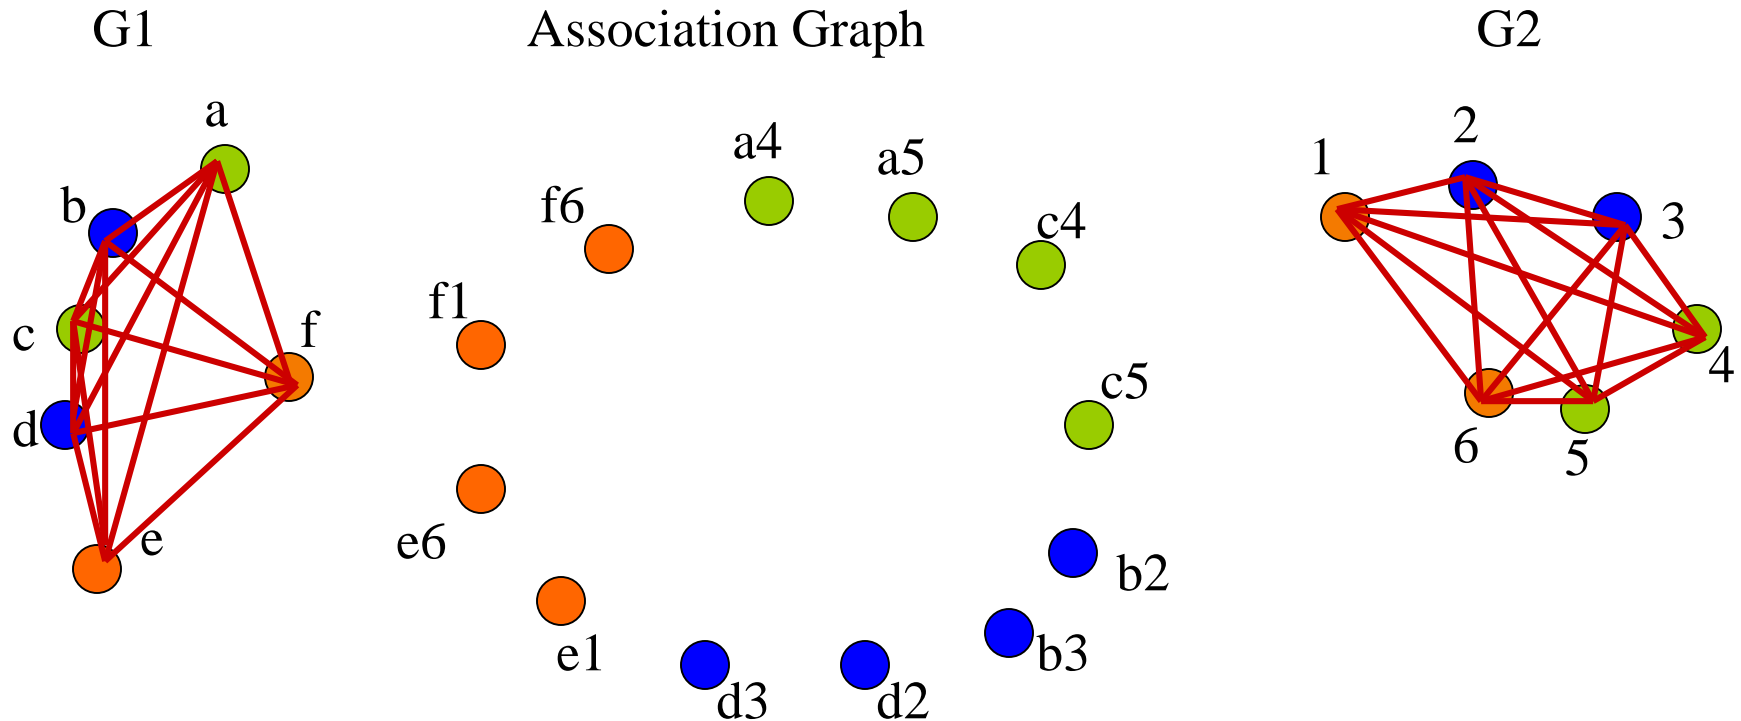

Association Graphs

- Depth
- Propensity
- Conservation
- Charge
- Hydrophobicity
- Secondary structure type
- Destabilization

Create vertices in the association graph for all **compatible** pairs of vertices in the original graphs. Compatibility could refer to chemical properties.

Association Graphs

Create edges between (uv) and (wx) if the edges between (u) and (w) as well as between (v) and (x) **match**.

Association Graphs

Create edges between (uv) and (wx) if the edges between (u) and (w) as well as between (v) and (x) **match**.

For this example, edge length is the only consideration

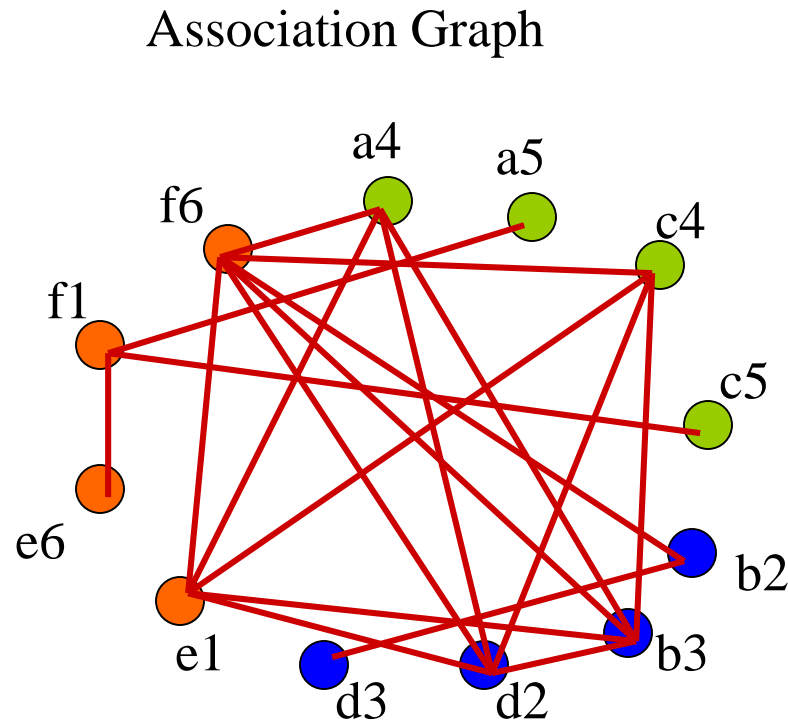

Association Graphs

Create edges between (uv) and (wx) if the edges between (u) and (w) as well as between (v) and (x) **match**.

For this example, edge length is the only consideration

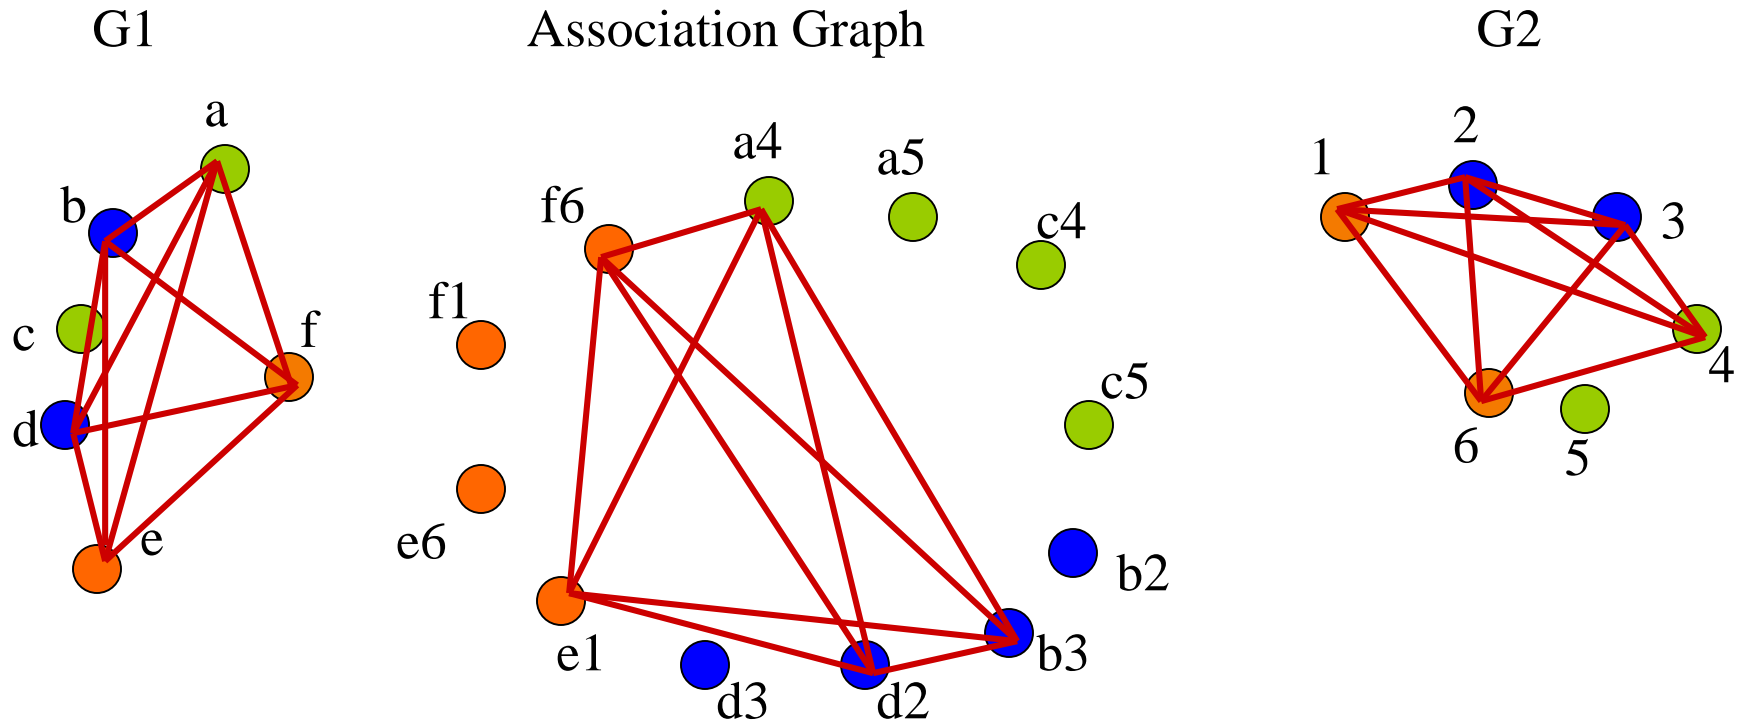

Association Graphs

Create edges between (uv) and (wx) if the edges between (u) and (w) as well as between (v) and (x) **match**.

For this example, edge length is the only consideration

Association Graphs

Finding correspondences: The the largest set of corresponding nodes in the same configuration is the **maximal clique** in the association graph

Association Graphs

Computational complexity:

- $O(2^n)$ for n points
- NP-complete
- Branch and bound algorithms

```
Find the Maximal Clique{
  return Cliques(empty, all nodes)
}

Cliques(X, Y){
  if (no node in Y-X is connected to all of X){
    return X;
  }else{
    y = node in Y connected to all of X;
    return Largest(Cliques(X union y, Y},
                  Cliques{X, Y-y});
  }
}
```

Generalized Hough Transform

Vote for transformations

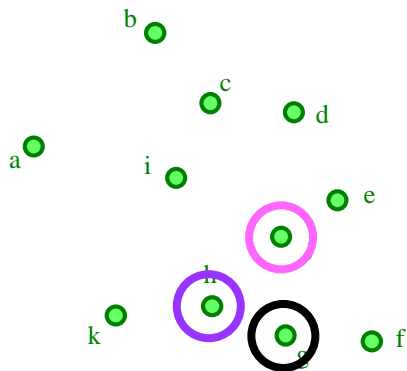

Generalized Hough Transform

Vote for transformations

Point Set A

Point Set B

Hough Transformation Space

Generalized Hough Transform

Simple to implement

- Can use grid to represent transformation space

Expensive for high-dimensional transformations

- Storage and number of samples is exponential in dimensionality of transformation space
 - Translation (3D)
 - Rotation (3D)
 - Translation & rotation (6D)
 - Translation & rotation & scale (7D)

Methods used for RGB-D scanning

Discussion

Iterative Closest Points

Given two point sets

Iterative Closest Points

Given two point sets

Iterative Closest Points

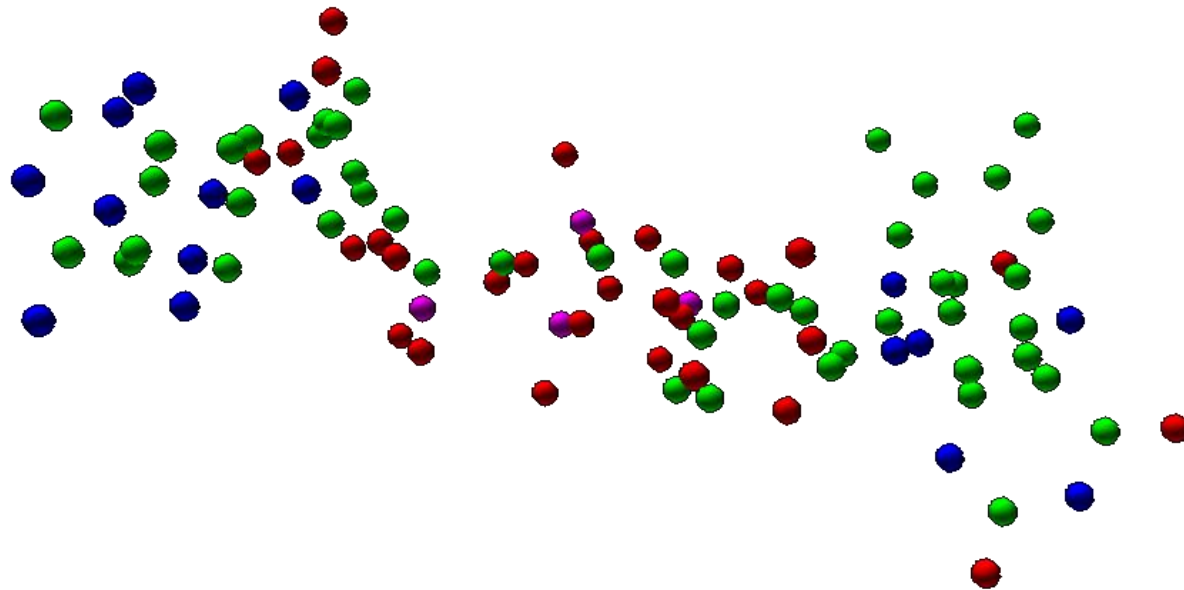

Given two point sets and an initial guess for the transformation that aligns them

Iterative Closest Points

Assume closest points correspond

Iterative Closest Points

Assume closest points correspond: $A \rightarrow B$

Iterative Closest Points

Assume closest points correspond: $A \rightarrow B$ and $B \rightarrow A$

Iterative Closest Points

Rejecting outliers

Iterative Closest Points

Find the transformation that optimally aligns proposed correspondences (superposition)

$$d(A, B) = \sum_{A_i \in A} \|A_i - B\|^2 + \sum_{B_i \in B} \|A_i - B\|^2$$

Iterative Closest Points

Iterate until convergence

1. Select source points (from one or both point sets)
2. Match to points in the other point set
3. Weight the correspondences
4. Reject outlier point pairs
5. Compute an error metric for the current transform
6. Minimize the error metric w.r.t. transformation

Computational complexity

- $O(k * n \log n)$ for n points per binding site and k iterations
 - k iterations * $O(n)$ points * $O(\log n)$ to find closest point

Summary

Brute force

- Accurate, slow

RANSAC

- Approximate

Geometric hashing

- Fast query, after slow preprocessing
- Distance threshold implicit in hash bucket sizes

Association graphs

- Expensive for large point sets
- Distance threshold for “associations”

Generalized Hough transform

- Requires lots of space/samples for high dimensional transformations

Iterative closest points

- Fast, in practice
- Requires good initial guess
