ANSI C Programming Language

- A small, general-purpose, initially systems programming language
 - Used for writing the UNIX OS and tools for many computers
 - Now also very popular for general-purpose computing
- A "low-level" language

datatypes and control structures are close to those on most machines

• Notable features

pointer (address) arithmetic and operators

all functions are call-by-value

simple, 2-level scope structure

no I/O or memory management facilities (provided by library routines)

"flexible" type structure

• History

C Program Structure

• <u>Programs</u>

are composed of one or more *files*

each file contains global variables and functions

```
/* this is the function "main" */
int main(int argc, char *argv[]) {
    hello();
    return 0;
}
/* this is the function "hello" */
void hello(void) {
    printf("hello world\n");
}
```

• Execution

begins by calling main

ends when main returns (or some function calls the library function exit)

• General form of an ANSI C function *definition*

```
[type]name(argument-declarations) { body }
int twice(int x, double y) {
    ...
}
```

- If no return value, type of function should be **void**.
- return statements specify function return values

```
int twice(int x, double y) {
    return 2*x + y;
}
```

• Unlike in Pascal, functions are never defined within functions

```

September 14, 1999
Declarations & Definitions

• <u>Declaration</u>: specifies (announces) the <u>properties</u> of an identifier

extern int sp;

extern int stack[];
```

specify that "sp is an int" and "stack is an array of ints"

```
extern indicates they are defined elsewhere
```

- outside this routine, or even outside this file
- <u>Definition</u>: declares the identifier <u>and</u> causes <u>storage</u> to be allocated

```
int sp = 1;
int stack[100];
```

declare sp and stack, allocates storage, sp is initialized to 1

- Can a variable have multiple declarations?
- Why does a language have declarations for variables?

- How do functions defined in different files communicate?
 - by calling one another (parameter passing and return values)
 - through global (externally declared) variables
- External variables

Externally declared versus extern?

Can we have multiple declarations of an externally defined variable within a file? What if an external declaration is not initialized? Is it treated as defined?

- So which functions and data may a function reference?
 - determined by the scope of identifiers

Global Variables & Scope

- The <u>scope</u> of an identifier says where the identifier can be used
- Functions can use global variables <u>declared</u> outside and above them

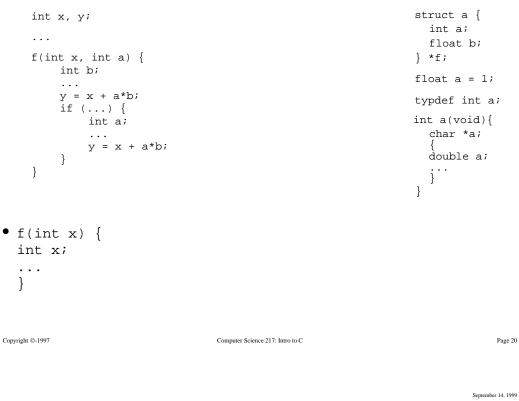

```
file a.c:
int stack[100];
main() {
   ...   stack is visible
}
int sp;
void push(int x) {
   ...   stack, sp are visible
}
```

Global variables and functions in other files are made avaiilable with extern

file b.c:

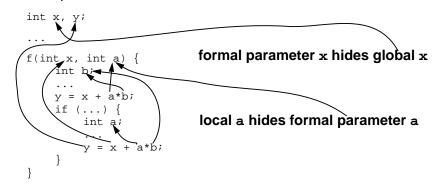

```
extern int stack[];
void dump(void) { ... }
stack defined in a.c is visible here
```

• Formal parameter and local declarations "hide" outer-level declarations

Scope, cont'd

• Formal parameter and local declarations "hide" outer-level declarations

- Cannot declare the same variable name *twice* in one scope
- f(int x) { int x; ... }
- Different <u>name spaces</u> allow same identifier to be multiply declared in a scope

 function and typdef names; labels; struct/union tags; struct/union members

Function Arguments and Local Variables

- <u>Local</u> variables are <u>temporary</u> variables (unless declared static)
 <u>created</u> upon entry to the function in which they are declared
 <u>destroyed</u> upon return
- <u>Arguments</u> are transmitted <u>by value</u>

the values of the arguments are *copied* into "local variables"

• Arguments are *initialized local variables*

```
int a, b;
                              void f(int a) {
main(void) {
                                  a = 3;
   a = 1; b = 2;
                                  {
   f(a);
                                      int b = 4;
   print(a, b);
                                     print(a, b);
}
                                  }
output:
                                  print(a, b);
                                  b = 5;
3 4
                               }
32
15
```

Function Declarations

· Declares the type of the value returned and the types of arguments

```
extern int f(int, float);
extern int f(int a, float b);
```

- A **void** function is a *procedure*
- A void argument list means *no* arguments

```
void hello(void)
```

- Unlike Pascal, functions can be used <u>before</u> they are declared as long as defined in same file or declared extern
- A function without a declaration

assumes the function returns an int

assumes arguments have the types of the corresponding expressions

```
"i = f(2.0, 1);" implies "int f(double, int);"
```

if f is defined otherwise, anything goes!

Static Variables

• static keyword in a declaration specifies

lifetime: static vs dynamic

scope: static vs global

• Static variables are

allocated at compile time and exist throughout program execution

• Statics are permanent, locals are temporary

```
void f(int v) {
   static int lastv = 0;
   print(lastv, v);
   lastv = v;
}
```

- Scope of static variables: within the file or block in which they are defined
 - scope versus lifetime
- What if a variable is declared extern inside a function?

```
Copyright ©-1997
```

Static Functions

Scope restricts the visibility of variables and functions

```
file stack.c:
```

<pre>static int sp; static int stack[100];</pre>	
<pre>static void bump(int n) { sp = sp + n; assert(sp >= 0 && sp < 100); }</pre>	
<pre>void push(int x) { bump(1); stack[sp] = x; } int pop(void) { bump(-1); return stack[sp+1]; }</pre>	sp & stack visible here, but not outside stack.c. so also function bump

• Static *functions* are visible only within the file in which they are defined

- Local variables have undefined values
- Need a variable to start with a particular value?
 - use an explicit initializer
- External and static variables are initialized to 0 by default
 - some consider it bad style to rely on this feature
