Java in 21 minutes

- · hello world
- · basic data types
- · classes & objects
- · program structure
- · constructors
- · garbage collection
- · I/O
- exceptions
- · Strings

Hello world

```
import java.io.*;
public class hello {
  public static void main(String[] args)
  {
     System.out.println("hello, world");
  }
}
```

- compiler creates hello.class
 - javac hello.java
- execution starts at main in hello.class
 java hello
- · filename has to match class name
- · libraries in packages loaded with import
 - java.lang is core of language
 System class contains stdin, stdout, etc.
 - java.io is basic I/O package
 file system access, input & output streams, ...

Basic data types

basic types:

- boolean true / false
- byte 8 bit signed
- char 16 bit unsigned (Unicode character)
- int 32 bit signed
- short, long, float, double

· String is sort of built in

- "..." is a String
- holds chars, NOT bytes
- does NOT have a null terminator
- + is string concatenation operator
- · System.out.println(s) is only for a single string
 - formatted output is a total botch

2 versions of echo

```
public class echo {
 public static void main(String[] args) {
   for (int i = 0; i < args.length; i++)</pre>
      if (i < args.length-1)</pre>
         System.out.print(args[i] + " ");
      else
         System.out.println(args[i]);
public class echo1 {
  public static void main(String[] args) {
     String s = "";
     for (int i = 0; i < args.length-1; i++)
         s += args[i] + " ";
     if (args.length > 0)
         s += args[args.length-1];
     if (s != "")
         System.out.println(s);
 }

    arrays have a length field (a.length)

  - subscripts are always checked
Strings have a length() function (s.length())
```

Classes, objects and all that

- · data abstraction and protection mechanism
- originally from Simula 67, via C++ and others

```
public part:
    methods: functions that define what operations
    can be done on this kind of object
    private part:
        functions and variables that implement the
        operation
}
```

- · defines a new data type "thing"
 - can declare variables and arrays of this type, pass to functions, return them, etc.
- · object: an instance of a class variable
- · method: a function defined within the class
 - (and visible outside)
- private variables and functions are not accessible from outside the class
- not possible to determine HOW the operations are implemented, only WHAT they do

Classes & objects

- · in Java, everything is part of some object
 - all classes are derived from class Object

- · member functions are defined inside the class
 - internal variables defined but shouldn't be public
 - internal functions shouldn't be public (e.g., matchhere)
- · all objects are created dynamically
- · have to call new to construct an object

```
RE re; // null: doesn't yet refer to an object
re = new RE("abc*"); // now it does
int m = re.match("abracadabra");
int start = re.start();
int end = re.end();
```

Constructors: making a new object

```
public RE(String re) {
    this.re = re;
}

RE r;
    r = new RE(s);
```

- "this" is the object being constructed or running the code
- · can use multiple constructors with different arguments to construct in different ways:

```
public RE() { /* ??? */ }
```

Class variables & instance variables

- · every object is an instance of some class
 - created dynamically by calling new
- · class variable: a variable declared static in class
 - only one instance of it in the entire program
 - exists even if the class is never instantiated
 - the closest thing to a global variable in Java

```
public class RE {
    static int num_REs = 0;

    public RE(String re) {
        num_REs++;
        ...
    }
```

· class methods

- most methods associated with an object instance
- if declared static, associated with class itself
- e.g., main()

Program structure

· typical structure is

```
class RE {
  private variables
  public RE methods, including constructor(s)
  private functions

public static void main(String[] args) {
    extract re
    for (i = 1; i < args.length; i++)
        fin = open up the file...
        grep(re, fin)
  }
  static int grep(String regexp, FileReader fin) {
    RE re = new RE(regexp);
    for each line of fin
        if (re.match(line)) ...
  }
}</pre>
```

· order doesn't matter

Destruction & garbage collection

- interpreter keeps track of what objects are currently in use
- · memory can be released when last use is gone
 - release does not usually happen right away
 - has to be garbage-collected
- · garbage collection happens automatically
 - separate low-priority thread manages garbage collection
- no control over when this happens
 - can set object reference to null to encourage it
- Java has no destructor (unlike C++)
 - can define a finalize() method for a class to reclaim other resources, close files, etc.
 - no guarantee that a finalizer will ever be called
- garbage collection is a great idea
 - but this is not a great design

I/O and file system access

- · import java.io.*
- · byte I/O
 - InputStream and OutputStream
- · character I/O (Reader, Writer)
 - InputReader and OutputWriter
 - InputStreamReader, OutputStreamWriter
 - BufferedReader, BufferedWriter
- · file access
- · buffering
- exceptions
- · in general, use character I/O classes

Character I/O

- · InputStreamReader reads Unicode chars
- · OutputStreamWriter write Unicode chars
- · use Buffered(Reader|Writer)
 - for speed
 - because it has a readLine method

```
public class cp4 {
public static void main(String[] args) {
 int b:
 try {
    BufferedReader bin = new BufferedReader(
        new InputStreamReader(
           new FileInputStream(args[0])));
     BufferedWriter bout = new BufferedWriter(
        new OutputStreamWriter(
           new FileOutputStream(args[1])));
     while ((b = bin.read()) > -1)
        bout.write(b);
     bin.close();
     bout.close();
 } catch (IOException e) {
     System.err.println("IOException " + e);
```

Line at a time I/O

```
public class cat3 {
public static void main(String[] args) {
   BufferedReader in = new BufferedReader(
      new InputStreamReader(System.in));
   BufferedWriter out = new BufferedWriter(
      new OutputStreamWriter(System.out));
   try {
      String s;
      while ((s = in.readLine()) != null) {
         out.write(s);
         out.newLine();
      }
      out.flush(); // required!!!
   } catch (Exception e) {
      System.err.println("IOException " + e);
   }
```

Exceptions

- · C-style error handling
 - ignore errors -- can't happen
 - return a special value from functions, e.g.,
 - -1 from system calls like open()
 NULL from library functions like fopen()
- · leads to complex logic
 - error handling mixed with computation
 - repeated code or goto's to share code
- · limited set of possible return values
 - extra info via errno and strerr: global data
 - some functions return all possible values
 no possible error return value is available
- Exceptions are the Java solution (also in C++)
- · exception indicates unusual condition or error
- · occurs when program executes a throw statement
- · control unconditionally transferred to catch block
- if no <u>catch</u> in current function, passes to calling method
- · keeps passing up until caught
 - ultimately caught by system at top level

```
try {...} catch {...}
```

· a method can catch exceptions

```
public void foo() {
    try {
        // if anything here throws an IO exception
        // or a subclass, like FileNotFoundException
} catch (IOException e) {
        // this code will be executed
        // to deal with it
}
```

- · or it can throw them, to be handled by caller
- · a method must list exceptions it can throw
 - exceptions can be thrown implicitly or explicitly

```
public void foo() throws IOException {
    // if anything here throws an exception
    // foo will throw an exception
    // to be handled by its caller
}
```

Why exceptions?

- reduced complexity
 - if a method returns normally, it worked
 - each statement in a **try** block knows that the previous statements worked, without explicit tests
 - if the try exits normally, all the code in it worked
 - error code grouped in a single place

· can't unconsciously ignore possibility of errors

 have to at least think about what exceptions can be thrown

String methods

· a String is sequence of Unicode chars

- immutable: each update makes a new String s += s2 makes a new s each time
- indexed from 0 to str.length()-1

· useful String methods

```
- charAt(pos) character at pos
```

- substring(start, len) substring

```
for (i = 0; i < s.length(); i++)
  if (s.charAt(i) != s.substring(i, 1))
    // can't happen</pre>
```

· String parsing

```
String[] fld = str.split("\\s+");
StringTokenizer st = new StringTokenizer(str)
while (st.hasMoreTokens()) {
   String s = st.nextToken();
   ...
}
```

"Real" example: regular expressions

- simple class to look like RE
- · uses the Java 1.4 regex mechanism
- provides a better interface (or at least less clumsy)

```
import java.util.regex.*;

public class RE {
         Pattern p;
         Matcher m;

    public RE(String pat) {
            p = Pattern.compile(pat);
        }
        public boolean match(String s) {
               m = p.matcher(s);
               return m.find();
        }
        public int start() {
              return m.start();
        }
        public int end() {
               return m.end();
        }
}
```

Java vs. C and C++

· no preprocessor

- import instead of #include
- constants use static final declaration

· C-like basic types, operators, expressions

sizes, order of evaluation are specified
 byte, short, int, long: signed integers (no unsigned)
 char: unsigned 16-bit Unicode character
 boolean: true or false

really object-oriented

- everything is part of some class
- objects all derived from Object class
- static member function applies to whole class

· references instead of pointers for objects

- null references, garbage collection, no destructors
- == is object identity, not content identity

· all arrays are dynamically allocated

- int[] a; a = new int[100];
- strings are more or less built in
- C-like control flow, but
 - labeled break and continue instead of goto
 - exceptions: try {...} catch(Exception) {...}

· threads for parallelism within a single process

- in language, not a library add-on
