## 3.1 SYMBOL TABLES

---

- ▶ API
- ▶ *elementary implementations*
- ▶ *ordered operations*

# Symbol tables

---

## Key-value pair abstraction.

- **Insert** a value with specified key.
- Given a key, **search** for the corresponding value.

## Ex. DNS lookup.

- Insert domain name with specified IP address.
- Given domain name, find corresponding IP address.

domain name	IP address
www.cs.princeton.edu	128.112.136.11
www.princeton.edu	128.112.128.15
www.yale.edu	130.132.143.21
www.harvard.edu	128.103.060.55
www.simpsons.com	209.052.165.60

↑  
key

↑  
value

# Symbol table applications

---

application	purpose of search	key	value
<b>dictionary</b>	find definition	word	definition
<b>book index</b>	find relevant pages	term	list of page numbers
<b>file share</b>	find song to download	name of song	computer ID
<b>financial account</b>	process transactions	account number	transaction details
<b>web search</b>	find relevant web pages	keyword	list of page names
<b>compiler</b>	find properties of variables	variable name	type and value
<b>routing table</b>	route Internet packets	destination	best route
<b>DNS</b>	find IP address	domain name	IP address
<b>reverse DNS</b>	find domain name	IP address	domain name
<b>genomics</b>	find markers	DNA string	known positions
<b>file system</b>	find file on disk	filename	location on disk

# Symbol tables: context

---

Also known as: maps, dictionaries, associative arrays.

Generalizes arrays. Keys need not be between 0 and  $N - 1$ .

Language support.

- External libraries: C, VisualBasic, Standard ML, bash, ...
- Built-in libraries: Java, C#, C++, Scala, ...
- Built-in to language: Awk, Perl, PHP, Tcl, JavaScript, Python, Ruby, Lua.

every array is an  
associative array

every object is an  
associative array

table is the only  
primitive data structure

```
hasNiceSyntaxForAssociativeArrays["Python"] = True  
hasNiceSyntaxForAssociativeArrays["Java"] = False
```

legal Python code

# Basic symbol table API

Associative array abstraction. Associate one value with each key.

```
public class ST<Key, Value>
```

```
ST()
```

*create an empty symbol table*

```
void put(Key key, Value val)
```

*put key-value pair into the table* ← **a[key] = val**

```
Value get(Key key)
```

*value paired with key* ← **a[key]**

```
boolean contains(Key key)
```

*is there a value paired with key?*

```
Iterable<Key> keys()
```

*all the keys in the table*

```
void delete(Key key)
```

*remove key (and its value) from table*

```
boolean isEmpty()
```

*is the table empty?*

```
int size()
```

*number of key-value pairs in the table*

# Conventions

---

- Values are not null. ← *java.util.Map allows null values*
- Method get() returns null if key not present.
- Method put() overwrites old value with new value.

## Intended consequences.

- Easy to implement contains().

```
public boolean contains(Key key)
{   return get(key) != null; }
```

- Can implement lazy version of delete().

```
public void delete(Key key)
{   put(key, null); }
```

# Keys and values

---

Value type. Any generic type.

Key type: several natural assumptions.

- Assume keys are Comparable, use compareTo().
- Assume keys are any generic type, use equals() to test equality.
- Assume keys are any generic type, use equals() to test equality; use hashCode() to scramble key.

specify Comparable in API.

built-in to Java  
(stay tuned)

Best practices. Use immutable types for symbol table keys.

- Immutable in Java: Integer, Double, String, java.io.File, ...
- Mutable in Java: StringBuilder, java.net.URL, arrays, ...

# Equality test

---

All Java classes inherit a method `equals()`.

**Java requirements.** For any references `x`, `y` and `z`:

- **Reflexive:** `x.equals(x)` is true.
  - **Symmetric:** `x.equals(y)` iff `y.equals(x)`.
  - **Transitive:** if `x.equals(y)` and `y.equals(z)`, then `x.equals(z)`.
  - **Non-null:** `x.equals(null)` is false.
-  equivalence relation

**Default implementation.** `(x == y)`

do `x` and `y` refer to  
the same object?

**Customized implementations.** `Integer`, `Double`, `String`, `java.io.File`, ...

**User-defined implementations.** Some care needed.

# Implementing equals for user-defined types

Seems easy.

```
public class Date implements Comparable<Date>
{
    private final int month;
    private final int day;
    private final int year;
    ...

    public boolean equals(Date that)
    {

        if (this.day != that.day) return false;
        if (this.month != that.month) return false;
        if (this.year != that.year) return false;
        return true;
    }
}
```

check that all significant  
fields are the same

# Implementing equals for user-defined types

Seems easy, but requires some care.

typically unsafe to use equals() with inheritance  
(would violate symmetry)

```
public final class Date implements Comparable<Date>
{
    private final int month;
    private final int day;
    private final int year;
    ...

    public boolean equals(Object y)
    {
        if (y == this) return true;           ← optimize for true object equality
        if (y == null) return false;         ← check for null
        if (y.getClass() != this.getClass())
            return false;                  ← objects must be in the same class
                                            (religion: getClass() vs. instanceof)

        Date that = (Date) y;
        if (this.day != that.day) return false;
        if (this.month != that.month) return false;   ← cast is guaranteed to succeed
        if (this.year != that.year) return false;
        return true;
    }
}
```

must be Object.  
Why? Experts still debate.

optimize for true object equality

check for null

objects must be in the same class  
(religion: getClass() vs. instanceof)

cast is guaranteed to succeed

check that all significant  
fields are the same

# Equals design

---

## "Standard" recipe for user-defined types.

- Optimization for reference equality.
- Check against null.
- Check that two objects are of the same type; cast.
- Compare each significant field:
  - if field is a primitive type, use == ← but use Double.compare() with double (to deal with -0.0 and NaN)
  - if field is an object, use equals() ← apply rule recursively
  - if field is an array, apply to each entry ← can use Arrays.deepEquals(a, b) but not a.equals(b)

## Best practices.

- No need to use calculated fields that depend on other fields.
- Compare fields mostly likely to differ first.
- Make compareTo() consistent with equals().

e.g., cached Manhattan distance

x.equals(y) if and only if (x.compareTo(y) == 0)

# ST test client for analysis

---

**Frequency counter.** Read a sequence of strings from standard input and print out one that occurs with highest frequency.

```
% more tinyTale.txt
it was the best of times
it was the worst of times
it was the age of wisdom
it was the age of foolishness
it was the epoch of belief
it was the epoch of incredulity
it was the season of light
it was the season of darkness
it was the spring of hope
it was the winter of despair
```

```
% java FrequencyCounter 3 < tinyTale.txt
the 10
```

```
% java FrequencyCounter 8 < tale.txt
business 122
```

```
% java FrequencyCounter 10 < leipzig1M.txt
government 24763
```

tiny example  
(60 words, 20 distinct)

real example  
(135,635 words, 10,769 distinct)

real example  
(21,191,455 words, 534,580 distinct)

# Frequency counter implementation

```
public class FrequencyCounter
{
    public static void main(String[] args)
    {
        int minlen = Integer.parseInt(args[0]);

        ST<String, Integer> st = new ST<String, Integer>(); ← create ST
        while (!StdIn.isEmpty())
        {
            String word = StdIn.readString(); ← ignore short strings
            if (word.length() < minlen) continue;
            if (!st.contains(word)) st.put(word, 1); ← read string and
            else                                st.put(word, st.get(word) + 1);
        }

        String max = "";                      print a string with max frequency
        st.put(max, 0);
        for (String word : st.keys())
            if (st.get(word) > st.get(max))
                max = word;
        StdOut.println(max + " " + st.get(max));
    }
}
```

## 3.1 SYMBOL TABLES

---

► API

► *elementary implementations*

► *ordered operations*

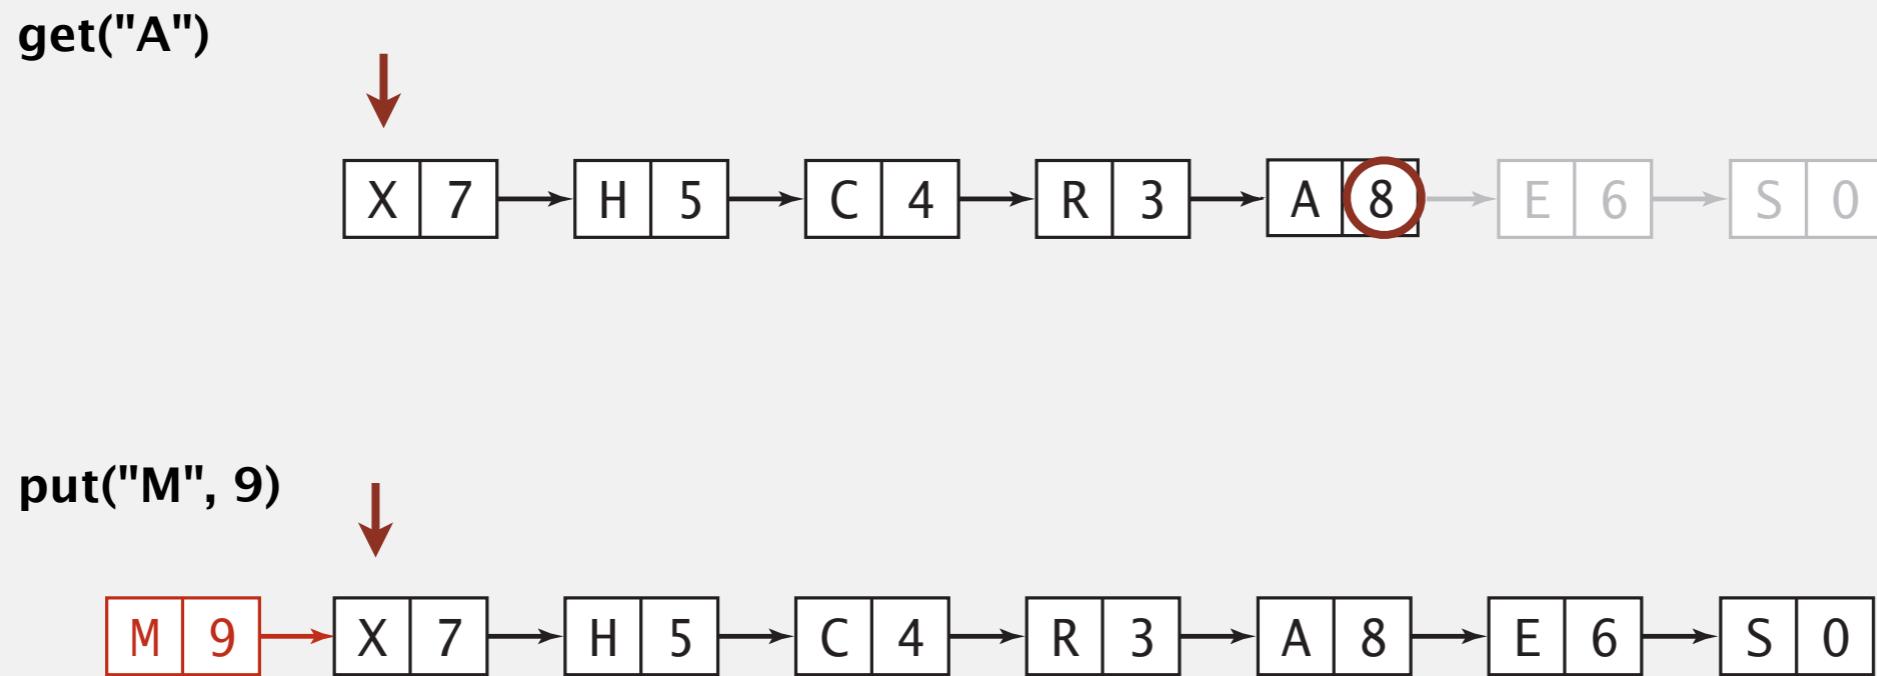

# Sequential search in a linked list

---

**Data structure.** Maintain an (unordered) linked list of key-value pairs.

**Search.** Scan through all keys until find a match.

**Insert.** Scan through all keys until find a match; if no match add to front.

# Elementary ST implementations: summary

---

implementation	guarantee		average case		operations on keys
	search	insert	search hit	insert	
<b>sequential search (unordered list)</b>	$N$	$N$	$N$	$N$	<code>equals()</code>

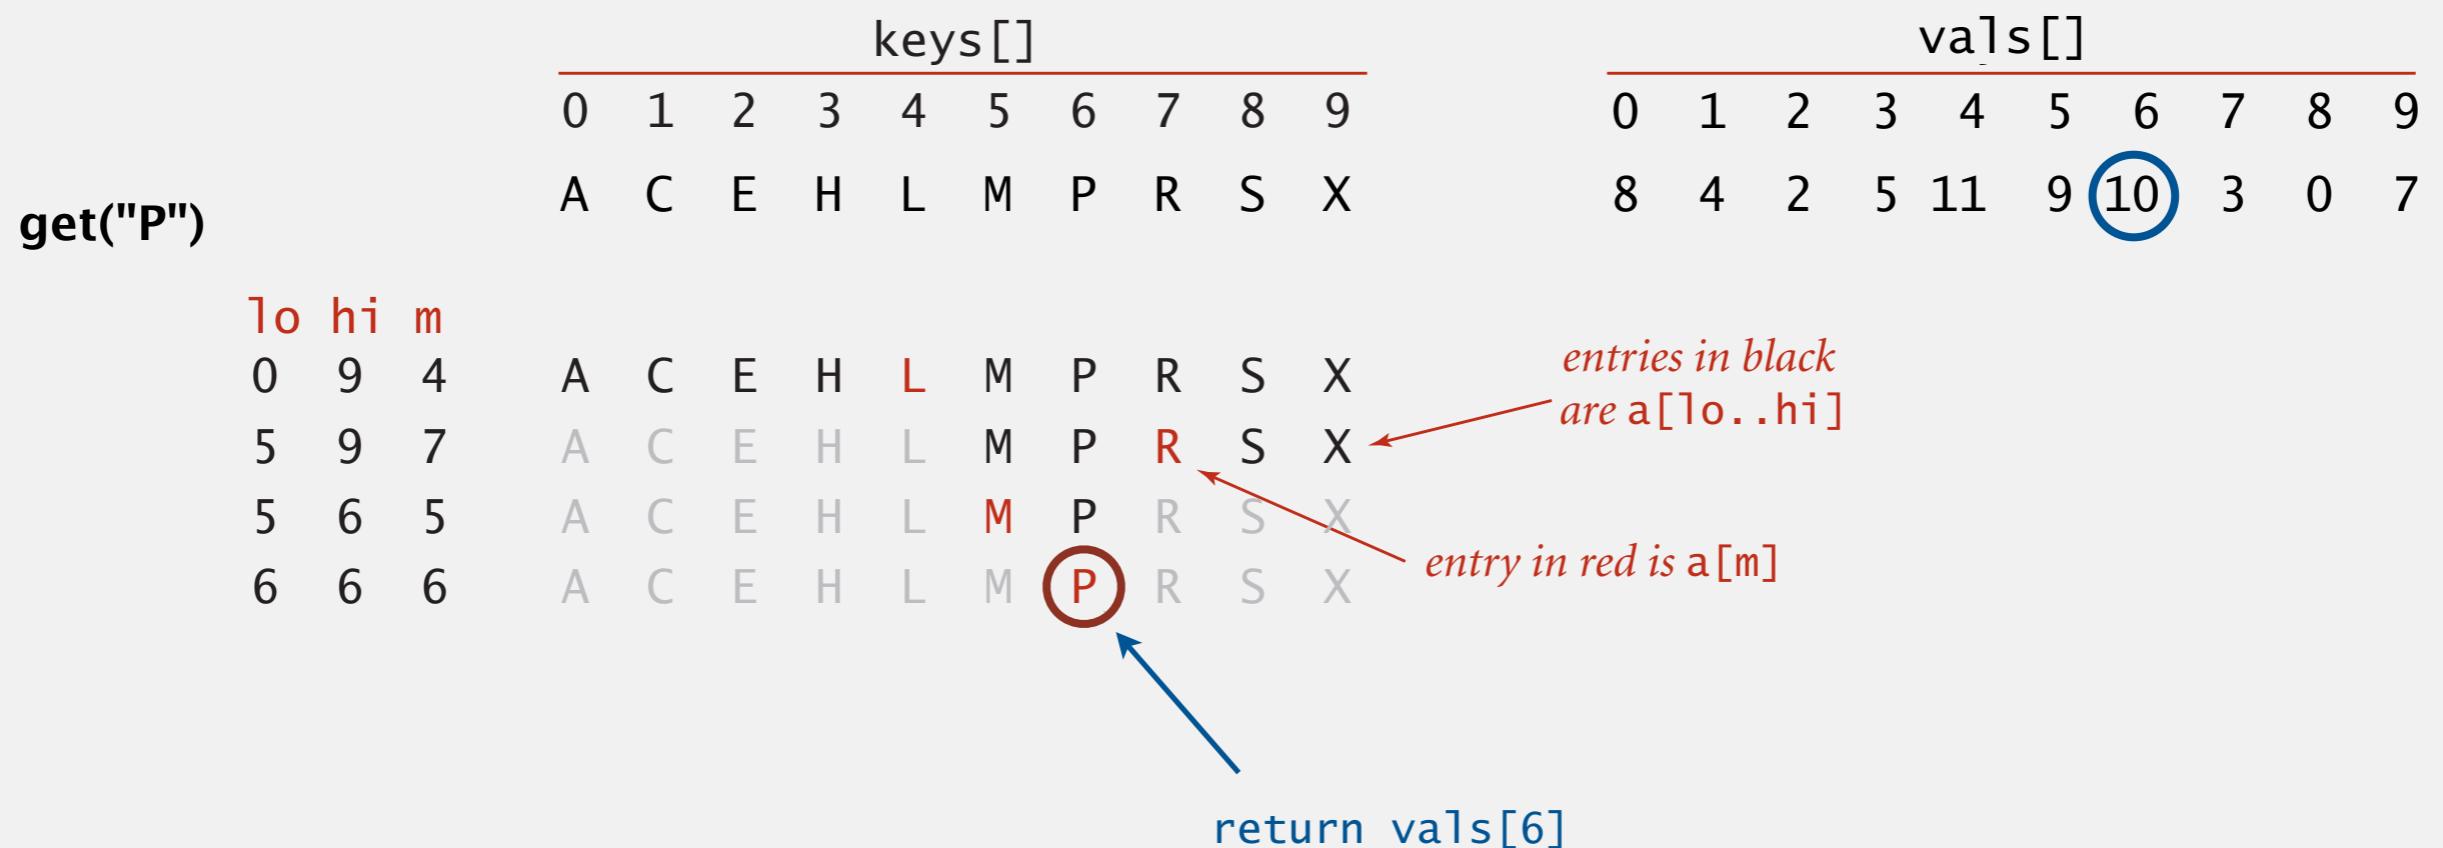

**Challenge.** Efficient implementations of both search and insert.

# Binary search in an ordered array

**Data structure.** Maintain parallel arrays for keys and values, sorted by keys.

**Search.** Use binary search to find key.

**Proposition.** At most  $\sim \lg N$  compares to search a sorted array of length  $N$ .

# Binary search in an ordered array

---

**Data structure.** Maintain parallel arrays for keys and values, sorted by keys.

**Search.** Use binary search to find key.

```
public Value get(Key key)
{
    int lo = 0, hi = N-1;
    while (lo <= hi)
    {
        int mid = lo + (hi - lo) / 2;
        int cmp = key.compareTo(keys[mid]);
        if (cmp < 0) hi = mid - 1;
        else if (cmp > 0) lo = mid + 1;
        else if (cmp == 0) return vals[mid];
    }
    return null; ← no matching key
}
```

## Elementary symbol tables: quiz 1

---

Implementing binary search was

- A. Easier than I thought.
- B. About what I expected.
- C. Harder than I thought.
- D. Much harder than I thought.
- E. *I don't know.*

# FIND THE FIRST 1

**Problem.** Given an array with all 0s in the beginning and all 1s at the end, find the index in the array where the 1s begin.

**N-1**

**input**

0	0	0	0	0	...	0	0	0	0	0	1	1	1	...	1	1	1	1
---	---	---	---	---	-----	---	---	---	---	---	---	---	---	-----	---	---	---	---

**Variant 1.** You are given the length of the array.

**Variant 2.** You are not given the length of the array.

## Binary search: insert

---

**Data structure.** Maintain an ordered array of key-value pairs.

**Insert.** Use binary search to find place to insert; shift all larger keys over.

**Proposition.** Takes linear time in the worst case.

`put("P", 10)`

keys[]										vals[]									
0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9
A	C	E	H	M	R	S	X	-	-	8	4	6	5	9	3	0	7	-	-

# Elementary ST implementations: summary

implementation	guarantee		average case		operations on keys
	search	insert	search hit	insert	
<b>sequential search (unordered list)</b>	$N$	$N$	$N$	$N$	<code>equals()</code>
<b>binary search (ordered array)</b>	$\log N$	$N^{\dagger}$	$\log N$	$N^{\dagger}$	<code>compareTo()</code>

† can do with  $\log N$  compares, but requires  $N$  array accesses

**Challenge.** Efficient implementations of both search and insert.
