Social Networks and Ranking

Generalized Social Networks

- Represent relationship between entities
 - paper cites paper
 - html page links to html page
 - A supervises B

directed graph

- A and B are friends
- papers share an author
- A and B are co-workers

undirected graph

Hypertext

- · document or part of document links to other parts or other documents
 - construct documents of interrelated pieces
 - relate documents to each other
- · pre-dates Web
- · Web "killer app."

How use links to improve information search?

- use structure to compute score for ranking
- · include more objects to rank - redefines "satisfying" of query?
- · can deal with objects of mixed types - images, PDF, ...

Scoring using structure

- Ideas
 - 1. link to object suggests it valuable object

2. distance between objects in graph represents degree of relatedness

reachable by all in 2 links

Pursuing linking and value

- Intuition: when Web page points to another Web page, it confers status/authority/ popularity to that page
- · Find a measure that captures intuition

· Not just web linking

- Citations in books, articles - Doctors referring to other doctors

Indegree

- Indegree = number of links into a node
- Most obvious idea: higher indegree => better node
- · Doesn't work well
- · Need some feedback in system
- · Leads us to Page and Brin's PageRank

7

PageRank

- Algorithm that gave Google the leap in quality
- Used link structure between pages in fundamental way to score pages
 - link structure centerpiece of scoring
- published

Page, Larry and Sergey Brin, R. Motwani, T. Winograd, The PageRank Citation Ranking: Bringing Order to the Web, Stanford Digital Library Technologies Project TR, Jan. 1998.

8

PageRank framework

- Given a directed graph with n nodes
- Assign each node a score that represents its importance in structure
 - Call score PageRank: pr(node)

9

Conferring importance

Core ideas:

- A node should confer some of its importance to the nodes to which it points
 - If a node is important, the nodes it links to should be important
- A node should not transfer more importance than it has

10

Attempt 1

Refer to nodes by numbers $1, \ldots, n$ (arbitrary numbering) Let t_i denote the number of edges out of *node* i (outdegree) Node i transfers $1/t_i$ of its importance on each edge out of it

4 1/3pr(1) 1/3pr(1)

Define

 $pr_{new}(k) = \sum_{i \text{ with edge from } i \text{ to } k} (pr(i) / t_i)$ Iterate until converges

Problems

- · Sinks (nodes with no edges out)
- · Cyclic behavior

11

1/2pr(2)

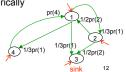

Attempt 2

Random walk model

- Attempt 1 gives movement from node to linked neighbor with probability 1/outdegree
- · Add random jump to any node

 $pr_{new}(k) = \alpha/n + (1-\alpha)\sum_{i \text{ with edge from } i \text{ to } k} (pr(i) / t_i)$

- $-\alpha$ parameter chosen empirically
- · Break cycles
- · Escape from sinks

Normalized?

- Would like $\sum_{1 \le k \le n} (pr(k)) = 1$
- Consider $\sum_{1 \le k \le n} (pr_{new}(k))$
 - = $\sum_{1 \le k \le n} (\alpha/n + (1-\alpha)\sum_{i \text{ with edge from } i \text{ to } k} (pr(i) / t_i))$
 - $= \sum_{1 \le k \le n} (\alpha/n) + \sum_{1 \le k \le n} ((1-\alpha) \sum_{i \text{ with edge from } i \text{ to } k} (pr(i) / t_i)) *$
 - + $(1-\alpha)\sum_{1 \le k \le n} \sum_{i \text{ with edge from i to } k} (pr(i) / t_i)$
 - + $(1-\alpha)\sum_{1 \le i \le n} \sum_{k \text{ with edge from i to } k} (pr(i) / t_i)$ α
 - + $(1-\alpha)\sum_{i \text{ with edge from } i} pr(i)$

*inner sum \sum_{i} over incoming

*inner sum $\sum_{\mathbf{k}}$ over outgoing edges for one i

Problem for desired normalization

Have

$$\sum_{1 \le k \le n} (pr_{new}(k)) = \alpha + (1-\alpha) \sum_{i \text{ with edge from } i} pr(i)$$

- Missing pr(i) for nodes with no edges from them
 - sinks!
- Solution: add n edges out of every sink
- Edge to every node including self
- Gives 1/n contribution to every node

Gives desired normalization:

If $\sum_{1 \le k \le n} (pr_{initial}(k)) = 1$ then $\sum_{1 \le k \le n} (pr(k)) = 1$

Matrix formulation

- · Let E be the n by n adjacency matrix E(i,k) = 1 if there is an edge from node i to node k = 0 otherwise
- Define new matrix L:

For each row i of E $(1 \le i \le n)$

If row i contains $t_i > 0$ ones, $L(i,k) = (1/t_i) E(i,k)$, $1 \le k \le n$ If row i contains 0 ones, L(i,k) = 1/n, $1 \le k \le n$

- Vector pr of PageRank values defined by
 - $pr = (\alpha/n, \alpha/n, \dots \alpha/n)^T + (1 \alpha) L^T pr$
- · has a solution representing the steady-state values pr(k)

Calculation

- Choose α
 - No single best value
 - Page and Brin originally used α =.15
- · Simple iterative calculation
 - Initialize $pr_{initial}(k) = 1/n$ for each node k
 - so $\sum_{1 \le k \le n} (pr_{\text{initial}}(k)) = 1$ $pr_{\text{new}}(k) = \alpha/n + (1-\alpha)\sum_{1 \le i \le n} L(i,k)pr(i)$
- Converges
 - Has necessary mathematical properties
 - In practice, choose convergence criterion
 - Stops iteration

PageRank Observations

- · Can be calculated for any directed graph
- Google calculates on entire Web graph
- query independent scoring
- · Huge calculation for Web graph
 - precomputed
 - 1998 Google published:
 - 52 iterations for 322 million links
 - 45 iterations for 161 million links
- · PageRank must be combined with querybased scoring for final ranking
 - Many variations
 - What Google exactly does secret
 - Can make some guesses by results

HITS

Hyperlink Induced Topic Search

- · Second well-known algorithm
- By Jon Kleinberg while at IBM Almaden Research Center
- · Same general goal as PageRank
- · Distinguishes 2 kinds of nodes
 - Hubs: resource pages
 - · Point to many authorities
 - Authorities: good information pages
 - · Point to many hubs

Mutual reinforcement

- Authority weight node j: a(j)
 - Vector of weights a
- Hub weight node j: h(j)
 - Vector of weights h
- Update:

$$a_{\text{new}}(k) = \sum_{i \text{ with edge from } i \text{ to } k} (h(i))$$

$$h_{\text{new}}(k) = \sum_{j \text{ with edge from k to } j} (a(j))$$

Matrix formulation

Steady state:

$$a = E^{T}h$$
 $a = E^{T}Ea$
 $h = Ea$ $h = EE^{T}h$

Interpretation:

- E^TE(i,j): number nodes point to both node i and node i
 - "Co-citation"
- EE^T(i,j): number nodes pointed to by both node i and node j
 - "Bibliographic coupling"

20

Iterative Calculation

```
a = h = (1, ..., 1)^{T}
While (not converged) {
a_{\text{new}} = E^{t}h
h_{\text{new}} = Ea
a = a_{\text{new}} / ||a_{\text{new}}|| normalize to unit vector
h = h_{\text{new}} / ||h_{\text{new}}|| normalize to unit vector
}
```

Provable convergence by linear algebra

21

Use of HITS

original use after find Web pages satisfying query:

- Retrieve documents satisfy query and rank by termbased techniques
- 2. Keep top c documents: root set of nodes
- c a chosen constant tunable
- Make base set:
 - a) Root set
 - b) Plus nodes pointed to by nodes of root set
 - c) Plus nodes pointing to nodes of root set

using links to expand

- Make base graph: base set plus edges from Web graph between these nodes
- 5. Apply HITS to base graph

22

Results using HITS

- Documents ranked by authority score a(doc) and hub score h(doc)
 - Authority score primary score for search results
- Heuristics:
 - delete all links between pages in same domain
 - Keep only pre-determined number of pages linking into root set (~200)
- · Findings (original paper)
 - Number iterations in original tests ~50
 - most authoritative pages do not contain initial query terms

graph

graph

• Kleinberg identified bad phenomena

• Base graph much smaller than Web

· HITS can be applied to any directed

- Topic diffusion: generalizes topic when expand root graph to base graph
 - example: want compilers generalized to programming

Observations

24

PageRank and HITS

- designed independently around 1997
- indicates time was ripe for this kind of analysis
- · lots of embellishments by others

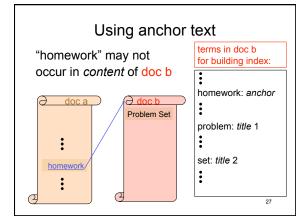

25

Revisit: How use links in ranking documents?

- use structure to compute score for ranking
 - PageRank, HITS
- · include more objects to rank
 - saw in use of HITS
- ➤use anchor text (HTML)
 - anchor text labels link
 - include anchor text

as text of document pointed to

26

Summary

- Link analysis
 - a principal component of ranking by modern
 Web search engines
 - must be combined with content analysis
- · Extend document content with link info
 - anchor text
 - text of URLs (e.g. princeton.edu, toxin.org)
- · Expand set of satisfying docs using links
 - less often used

28
