1

Data Types and Data Structures

Data types. Set of values and operations on those values.

- Some are built into the Java language: int, double[], String, ...
- Most are not: Complex, Picture, Stack, Queue, ST, Graph, ...

↑ this lecture ↑ next lecture

Data structures.

- Represent data or relationships among data.
- Some are built into Java language: arrays.
- Most are not: linked list, circular list, tree, sparse array, graph, ...

↑ this lecture ↑ TSP assignment ↑ next lecture

2

Collections

Fundamental data types.

- Set of operations (add, remove, test if empty) on generic data.
- Intent is clear when we insert.
- Which item do we remove?

Stack. [LIFO = last in first out]

← this lecture

- Remove the item most recently added.
- Ex: cafeteria trays, Web surfing.

Queue. [FIFO = first in, first out]

← this lecture

- Remove the item least recently added.
- Ex: Hoagie Haven line.

Symbol table.

← next lecture

- Remove the item with a given key.
- Ex: Phone book.

3

Stacks

4

Stack API

```
public class *StackOfStrings
{
    *StackOfStrings() create an empty stack
    boolean isEmpty() is the stack empty?
    void push(String item) push a string onto the stack
    String pop() pop the stack
}
```

Stack Client Example 1: Reverse

```
public class Reverse {
    public static void main(String[] args) {
        StackOfStrings stack = new StackOfStrings();
        while (!StdIn.isEmpty()) {
            String s = StdIn.readString();
            stack.push(s);
        }
        while (!stack.isEmpty()) {
            String s = stack.pop();
            StdOut.println(s);
        }
    }
}
```

```
% more tiny.txt
it was the best of times

% java Reverse < tiny.txt
times of best the was it
```

Stack Client Example 2: Test Client

```
public static void main(String[] args) {
    StackOfStrings stack = new StackOfStrings();
    while (!StdIn.isEmpty()) {
        String s = StdIn.readString();
        if (s.equals("-"))
            StdOut.println(stack.pop());
        else
            stack.push(s);
    }
}
```

```
% more test.txt
to be or not to - be - - that - - - is

% java StackOfStrings < test.txt
to be not that or be
```

Stack: Array Implementation

Array implementation of a stack.

- Use array `a[]` to store `N` items on stack.
- `push()` add new item at `a[N]`.
- `pop()` remove item from `a[N-1]`.

```
public class ArrayStackOfStrings {
    private String[] a;
    private int N = 0;
    public ArrayStackOfStrings(int max) { a = new String[max]; }
    public boolean isEmpty() { return (N == 0); }
    public void push(String item) { a[N++] = item; }
    public String pop() { return a[--N]; }
}
```

Array Stack: Test Client Trace

	StdIn	StdOut	N	a[]				
				0	1	2	3	4
			0					
push	to		1	to				
	be		2	to	be			
	or		3	to	be	or

	-	be	1	to	be	or	that	be
	is		2	to	is	or	not	to

9

Array Stack: Performance

Running time. Push and pop take constant time.

Memory. Proportional to client-supplied capacity, not number of items.

Problem.

- Original API does not take capacity as argument (bad to change API).
- Client might not know what capacity to use.
- Client might use multiple stacks.

Challenge. Stack where capacity is not known ahead of time.

10

Linked Lists

Sequential vs. Linked Allocation

Sequential allocation. Put items one after another.

- TOY: consecutive memory cells.
- Java: array of objects.

Linked allocation. Include in each object a link to the next one.

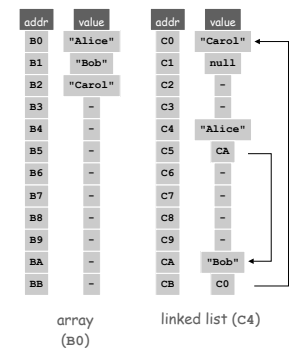

- TOY: link is memory address of next item.
- Java: link is reference to next item.

Key distinctions.

- Array: random access, fixed size.
- Linked list: sequential access, variable size.

← get ith item

← get next item

11

10

Linked Lists

Linked list.

- A recursive data structure.
- An item plus a pointer to another linked list (or empty list).
- Unwind recursion: linked list is a sequence of items.

Node data type.

- A reference to a String.
- A reference to another Node.

```
private class Node {
    private String item;
    private Node next;
}
```

why private?

13

Building a Linked List

```
Node third = new Node();
third.item = "Carol";
third.next = null;

Node second = new Node();
second.item = "Bob";
second.next = third;

Node first = new Node();
first.item = "Alice";
first.next = second;
```

14

Linked List Demo

```
Node third = new Node();
third.item = "Carol";
third.next = null;

Node second = new Node();
second.item = "Bob";
second.next = third;

Node first = new Node();
first.item = "Alice";
first.next = second;
```

16

List Processing Challenge 1

Q. What does the following code fragment do?

```
Node last = new Node();
last.item = StdIn.readString();
last.next = null;
Node first = last;
while (!StdIn.isEmpty()) {
    last.next = new Node();
    last = last.next;
    last.item = StdIn.readString();
    last.next = null;
}
```

17

List Processing Challenge 2

Q. What does the following code fragment do?

```
for (Node x = first; x != null; x = x.next) {
    StdOut.println(x.item);
}
```

18

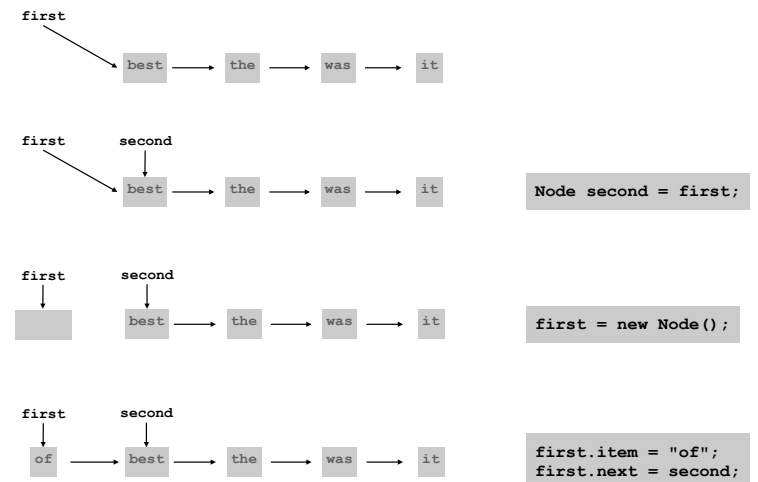

Enough with the Idioms

How about this idea:

- Use a linked list to implement a stack

Stack Pop: Linked List Implementation

22

Linked List Stack: Test Client Trace

23

Stack Data Structures: Tradeoffs

Two data structures to implement stack data type.

Array.

- Every push/pop operation take constant time.
- **But...** must fix maximum capacity of stack ahead of time.

Linked list.

- Every push/pop operation takes constant time.
- Memory is proportional to number of items on stack.
- **But...** uses extra space and time to deal with references.

24

Parameterized Data Types

25

Stack: Linked List Implementation

```
public class LinkedStackOfStrings {
    private Node first = null;

    private class Node {
        private String item;
        private Node next;
    } // "inner class"

    public boolean isEmpty() { return first == null; }

    public void push(String item) {
        Node second = first;
        first = new Node();
        first.item = item;
        first.next = second;
    }

    public String pop() {
        String item = first.item;
        first = first.next;
        return item;
    }
}
```

26

Parameterized Data Types

We just implemented: `StackOfStrings`.

We also want: `StackOfInts`, `StackOfURLs`, `StackOfVans`, ...

Strawman. Implement a separate stack class for each type.

- Rewriting code is tedious and **error-prone**.
- Maintaining cut-and-pasted code is tedious and **error-prone**.

27

Generics

Generics. Parameterize stack by a single type.

```
Stack<Apple> stack = new Stack<Apple>();
Apple a = new Apple();
Orange b = new Orange();
stack.push(a);
stack.push(b); // compile-time error
a = stack.pop();
```

sample client

can't push an orange onto
a stack of apples

28

Generic Stack: Linked List Implementation

```
public class Stack<Item> {
    private Node first = null;

    private class Node {
        private Item item;
        private Node next;
    }

    public boolean isEmpty() { return first == null; }

    public void push(Item item) {
        Node second = first;
        first = new Node();
        first.item = item;
        first.next = second;
    }

    public Item pop() {
        Item item = first.item;
        first = first.next;
        return item;
    }
}
```

parameterized type name
(chosen by programmer)

29

Autoboxing

Generic stack implementation. Only permits reference types.

Wrapper type.

- Each primitive type has a **wrapper** reference type.
- Ex: Integer is wrapper type for int.

Autoboxing. Automatic cast from primitive type to wrapper type.

Auto-unboxing. Automatic cast from wrapper type to primitive type.

```
Stack<Integer> stack = new Stack<Integer>();
stack.push(17); // autobox (int -> Integer)
int a = stack.pop(); // auto-unbox (Integer -> int)
```

30

Stack Applications

Real world applications.

- Parsing in a compiler.
- Java virtual machine.
- Undo in a word processor.
- Back button in a Web browser.
- PostScript language for printers.
- Implementing function calls in a compiler.

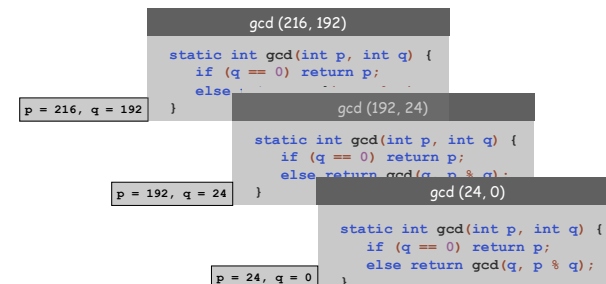

31

Function Calls

How a compiler implements functions.

- Function call: **push** local environment and return address.
- Return: **pop** return address and local environment.

Recursive function. Function that calls itself.

Note. Can always use an explicit stack to remove recursion.

32

Arithmetic Expression Evaluation

Goal. Evaluate infix expressions.

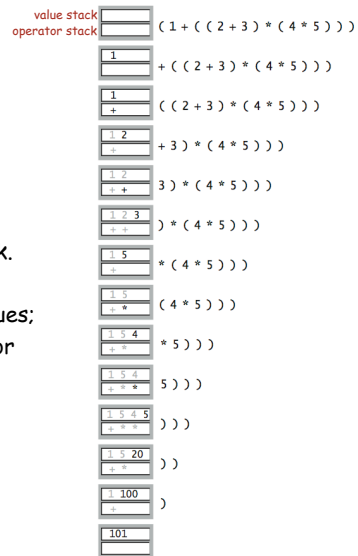

(1 + ((2 + 3) * (4 * 5)))

operand operator

Two stack algorithm. [E. W. Dijkstra]

- Value: push onto the value stack.
- Operator: push onto the operator stack.
- Left parens: ignore.
- Right parens: pop operator and two values; push the result of applying that operator to those values onto the value stack.

Context. An interpreter!

33

Arithmetic Expression Evaluation

```
public class Evaluate {
    public static void main(String[] args) {
        Stack<String> ops = new Stack<String>();
        Stack<Double> vals = new Stack<Double>();
        while (!StdIn.isEmpty()) {
            String s = StdIn.readString();
            if (s.equals("(")) ;
            else if (s.equals("+")) ops.push(s);
            else if (s.equals("*")) ops.push(s);
            else if (s.equals(")") {
                String op = ops.pop();
                if (op.equals("+")) vals.push(vals.pop() + vals.pop());
                else if (op.equals("*")) vals.push(vals.pop() * vals.pop());
            }
            else vals.push(Double.parseDouble(s));
        }
        StdOut.println(vals.pop());
    }
}
```

```
% java Evaluate
( 1 + ( ( 2 + 3 ) * ( 4 * 5 ) ) )
101.0
```

34

Correctness

Why correct? When algorithm encounters an operator surrounded by two values within parentheses, it leaves the result on the value stack.

(1 + ((2 + 3) * (4 * 5)))

So it's as if the original input were:

(1 + (5 * (4 * 5)))

Repeating the argument:

(1 + (5 * 20))
 (1 + 100)
 101

Extensions. More ops, precedence order, associativity, whitespace.

1 + (2 - 3 - 4) * 5 * sqrt(6*6 + 7*7)

35

Stack-Based Programming Languages

Observation 1. Remarkably, the 2-stack algorithm computes the same value if the operator occurs **after** the two values.

(1 ((2 3 +) (4 5 *) *) +)

Observation 2. All of the parentheses are redundant!

1 2 3 + 4 5 * * +

Jan Lukasiewicz

Bottom line. Postfix or "reverse Polish" notation.

Applications. Postscript, Forth, calculators, Java virtual machine, ...

Queues

Queue API

```
public class Queue<Item>
    Queue<Item>()           create an empty queue
    boolean isEmpty()      is the queue empty?
    void enqueue(Item item) enqueue an item
    Item dequeue()         dequeue an item
    int length()           queue length
```

```
public static void main(String[] args) {
    Queue<String> q = new Queue<String>();
    q.enqueue("Vertigo");
    q.enqueue("Just Lose It");
    q.enqueue("Pieces of Me");
    q.enqueue("Pieces of Me");
    while(!q.isEmpty())
        StdOut.println(q.dequeue());
}
```

Enqueue: Linked List Implementation

```
Node oldlast = last;
```

```
last = new Node();
last.item = "of";
last.next = null;
```

```
oldlast.next = last;
```

Dequeue: Linked List Implementation

```
String item = first.item;
```

```
first = first.next;
```

```
return item;
```

Queue: Linked List Implementation

```
public class Queue<Item> {
    private Node first, last;
    private class Node { Item item; Node next; }

    public boolean isEmpty() { return first == null; }

    public void enqueue(Item item) {
        Node oldlast = last;
        last = new Node();
        last.item = item;
        last.next = null;
        if (isEmpty()) first = last;
        else oldlast.next = last;
    }

    public Item dequeue() {
        Item item = first.item;
        first = first.next;
        if (isEmpty()) last = null;
        return item;
    }
