The 3D Rasterization Pipeline

3D Rendering Scenarios

• Batch
  ◦ One image generated with as much quality as possible for a particular set of rendering parameters
    ▪ Take as much time as is needed (minutes)
    ▪ Useful for photorealism, movies, etc.

➢ Interactive
  ◦ Images generated in fraction of a second (<1/10) with user input, animation, varying camera, etc.
    ▪ Achieve highest quality possible in given time
    ▪ Visualization, games, etc.
Many applications use rendering of 3D polygons with direct illumination.

Ray Casting Revisited

• For each sample …
  - Construct ray from eye position through view plane
  - Find first surface intersected by ray through pixel
  - Compute color of sample based on illumination
3D Polygon Rendering

- We can render polygons faster if we take advantage of spatial coherence

OpenGL executes steps of 3D rendering pipeline for each polygon

```c
glBegin(GL_POLYGON);
GLfloat vertex[] = {0.0, 0.0, 0.0};
GLfloat vertex2[] = {1.0, 0.0, 0.0};
GLfloat vertex3[] = {0.0, 1.0, 0.0};
glEnd();

Review: Viewing Transformation

- Mapping from world to camera coordinates
  - Eye position maps to origin
  - Right vector maps to X axis
  - Up vector maps to Y axis
  - Back vector maps to Z axis
Review: Camera Coordinates

- Canonical coordinate system
  - Convention is right-handed (looking down \(-z\) axis)
  - Convenient for projection, clipping, etc.

- Camera right vector maps to X axis
- Camera up vector maps to Y axis
- Camera back vector maps to Z axis (pointing out of page)
Finding the viewing transformation

- We have the camera (in world coordinates)
- We want $T$ taking objects from world to camera

$$p^c = T \ p^w$$

- Trick: find $T^{-1}$ taking objects in camera to world

$$p^w = T^{-1} p^c$$

$$\begin{bmatrix} x' \\ y' \\ z' \\ w' \end{bmatrix} = \begin{bmatrix} a & b & c & d \\ e & f & g & h \\ i & j & k & l \\ m & n & o & p \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ w \end{bmatrix}$$
Finding the Viewing Transformation

- Trick: map from camera coordinates to world
  - Origin maps to eye position
  - Z axis maps to Back vector
  - Y axis maps to Up vector
  - X axis maps to Right vector

\[
\begin{bmatrix}
x'
y'
z'
w'
\end{bmatrix}
= \begin{bmatrix}
R_x & U_x & B_x & E_x \\
R_y & U_y & B_y & E_y \\
R_z & U_z & B_z & E_z \\
R_w & U_w & B_w & E_w \\
\end{bmatrix}
\begin{bmatrix}
x \\
y \\
z \\
w \\
\end{bmatrix}
\]

- This matrix is $T^{-1}$ so we invert it to get $T$ ... easy!

Projection

• General definition:
  ○ Transform points in $n$-space to $m$-space ($m<n$)

• In computer graphics:
  ○ Map 3D camera coordinates to 2D screen coordinates

Perspective vs. Parallel

- **Perspective projection**
  - Size varies inversely with distance - looks realistic
  - Distance and angles are not (in general) preserved
  - Parallel lines do not (in general) remain parallel

- **Parallel projection**
  - Good for exact measurements
  - Parallel lines remain parallel
  - Angles are not (in general) preserved
  - Less realistic looking
Transformations map points from one coordinate system to another.
Viewport Transformation

- Transform 2D geometric primitives from screen coordinate system (normalized device coordinates) to image coordinate system (pixels)
Viewport Transformation

- Window-to-viewport mapping

\[
\begin{align*}
v_x &= vx_1 + (wx - wx_1) \times (vx_2 - vx_1) / (wx_2 - wx_1); \\
v_y &= vy_1 + (wy - wy_1) \times (vy_2 - vy_1) / (wy_2 - wy_1); \\

Clipping

- Avoid drawing parts of primitives outside window
  - Window defines part of scene being viewed
  - Must draw geometric primitives only inside window
Polygon Clipping

Antialiased Scan Conversion
Scan Conversion

- Render an image of a geometric primitive by setting pixel colors

```c
void SetPixel(int x, int y, Color rgba)
```

- Example: Filling the inside of a triangle
Triangle Scan Conversion

- Properties of a good algorithm
  - Symmetric
  - Straight edges
  - No cracks between adjacent primitives
  - (Antialiased edges)
  - FAST!
Simple Algorithm

• Color all pixels inside triangle

```c
void ScanTriangle(Triangle T, Color rgba){
    for each pixel P in bbox(T){
        if (Inside(T, P))
            SetPixel(P.x, P.y, rgba);
    }
}
```
Triangle Sweep-Line Algorithm

• Take advantage of spatial coherence
  ◦ Compute which pixels are inside using horizontal spans
  ◦ Process horizontal spans in scan-line order

• Take advantage of edge linearity
  ◦ Use edge slopes to update coordinates incrementally
void ScanTriangle(Triangle T, Color rgba){
    for each edge pair {
        initialize $x_L$, $x_R$;
        compute $dx_L/dy_L$ and $dx_R/dy_R$;
        for each scanline at $y$
            for (int $x = x_L$; $x <= x_R$; $x++$)
                SetPixel($x$, $y$, rgba);
        $x_L += dx_L/dy_L$;
        $x_R += dx_R/dy_R$;
    }
}
void ScanTriangle(Triangle T, Color rgba) {
    for each edge pair {
        x_L, x_R;
        compute dx_L/dy_L and dx_R/dy_R;
        for each scanline at y
