COS 226 Midterm Review Spring 2016

guna@cs.princeton.edu

Time and location:

- The midterm is during lecture on
 - Wednesday March 9th from 11-12:20pm.
- The exam will start and end promptly, so please do arrive on time.
- The midterm room is
 - The midterm rooms are
 - Precepts P01, P02, P02A, P03, P03A, P04, P05: McCosh10 (traditional lecture room)
 - Precepts P06, P07, P07A: MCCOH46 (new room)
 - Flipped Lecture/P99: Jadwin A10 (flipped lecture room)
- Failure to go to the right room can result in a serious deduction on the exam. There will be no makeup exams except under extraordinary circumstances, which must be accompanied by the recommendation of a Dean.

Rules

- Closed book, closed note.
- You may bring one 8.5-by-11 sheet (one side)
 with notes in your <u>own handwriting</u> to the
 exam.
- No electronic devices (including calculators, laptops, and cell phones).

Material covered

- Algorithms, 4th edition, Sections 1.3–1.5,
 Chapter 2, and Chapter 3.
- *Lectures* 1–10
- Programming assignments 1–4.

concepts (so far)

List of algorithms and data structures:

quick-find

quick-union

weighted quick-union

resizing arrays

linked lists

stacks

queues

insertion sort

selection sort

Knuth shuffle

mergesort

bottom-up mergesort

quicksort

3-way quicksort

quickselect

binary heaps

heapsort

sequential search

binary search

BSTs

2-3 trees

left-leaning red-black BSTs

Hashing – linear probing, separate chaining

Analysis of algorithms

useful formulas

$$1 + 2 + ... + N$$
.

$$\sum_{i=1}^{N} i \sim \int_{x=1}^{N} x \, dx \sim \frac{1}{2} N^2$$

$$1^k + 2^k + \ldots + N^k.$$

$$\sum_{i=1}^{N} i^{k} \sim \int_{x=1}^{N} x^{k} dx \sim \frac{1}{k+1} N^{k+1}$$

$$1 + 1/2 + 1/3 + \dots + 1/N$$
.

$$\sum_{i=1}^{N} \frac{1}{i} \sim \int_{x=1}^{N} \frac{1}{x} dx = \ln N$$

3-sum triple loop.

$$\sum_{i=1}^{N} \sum_{j=i}^{N} \sum_{k=j}^{N} 1 \sim \int_{x=1}^{N} \int_{y=x}^{N} \int_{z=y}^{N} dz \, dy \, dx \sim \frac{1}{6} N^{3}$$

$$\sum_{i=0}^{\infty} \left(\frac{1}{2}\right)^i = 2$$

$$\sum_{i=1}^{n} r^{i-1} = \left(\frac{1-r^n}{1-r}\right)$$

$$| + 2 + 2 + 2 + 2 = 2 - 1$$

Union-Find

 A data structure that supports two operations, union and find

• Applications – Connectivity

Three models

	Union	Find	space
Quick-union		N	N
Quick-Find	N		N
Weighted Quick- Union	1051	(o5 N	N

Weighted quick-union

Core ideas of weighted union-find

- The tree height must be logarithmic
- when trees are combined smaller tree is attached to larger tree
- only instance that height of a tree increase is when two trees are the same height

Circle the letters corresponding to arrays that cannot possibly occur during the execution of

i: 0 1 2 3 4 5 6 7 8 9

A. a[i]: 1 2 3 0 1 1 1 4 4 5

B. a[i]: 9 0 0 0 0 0 9 9 9 9

C. a[i]: 1 2 3 4 5 6 7 8 9 9 9

Provide an order in which elements in fare possibly added to union-find. Do the same for B and C.

Sorting

IA	2A 1B 2B 1C 2A Sorting questions
17	Which operations is performed the most in general? Compares or exchanges?
IA	2A 1B 2B 1C Conpare
•	Which sorting algorithms have the best case order of growth O(N)?
•	Which sorting algorithms have the worst case order of growth O(N)?
•	Which sorting algorithms have the average/worst case order of growth $O(N^2)$?
•	Which sorting algorithms have the best/average/worst case order of growth O(N log N)?
	mosk swy
•	Which sorting algorithms are stable? Which sorting algorithms are stable?
•	If names array (first name, last name) are sorted in "standard order", what comparators should we use and in what order?
	nanc. First Name, nanc. Last Name
•	Which sorting algorithms are in-place? Which sorting algorithms are in-place?
•	Which sorting algorithms do the least amount of exchanges?
	Sellchin a, az az az az
	9,925,97

Further invariants:

2. Insertion: A[i+1...N-1] is the

original

3. Selection: A[0...i] are the smallest in the array and are in the final position

4. Mergesort: A[0..i] is sorted and

 $I = 2^k$ for some k

1

2-way and 3-way quicksort

The pivot (first entry) is placed in the final position

- **2-way** All elements to the left are <= and right are >=
- 3-way All elements equal to pivot are in the middle. Left is < and right is >
- How can one recognize 2-way from 3-way if first entry has no duplicates?
 - 2-way does not swap a lot and do one swap of the pivot at the end.
 That is, all elements <= pivot must stay in their original position and all elements >= must stay in their original position
 - 3-way takes the pivot with it and making swaps. All elements < have moved to the left as pivot moves forward

2-way or 3-way?

not by

Mystery function

```
public Key mystery (Key key
   Node best = mystery(root, key, null);
   if (best == null) return null;
   return best.key;
}
private Node mystery(Node x, Key key, Node best
   if (x == null) return best;
   int cmp = key.compareTo(x.key);
           (cmp < 0) return mystery(x left, key, x);
   if
   else if (cmp > 0) return mystery(x.right) key, best);
   else
                     return x;
      mystery is the ceiling function
```

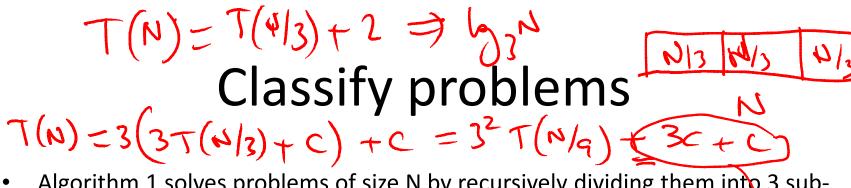

Analysis of Algorithms

Analysis of Algorithms

- Performance of an algorithm is measured using
 - comparisons, array accesses, exchanges,
 - memory requirements
- best, worst, average
 - Performance measure based on some specific input type
 - Eg: sorted, random, reverse sorted. Almost sorted

Order of Growth (average/worst)

	insert	delete	search	findMax	findMin	Find kth smallest
Unsorted arrays	IN	NN	N	7	N	KN
Sorted arrays	N	N	10501			
BST	ly of N	W.	<u> </u>	¬ ~	7	5 K
LLRB	1001	10/0	100	(0,1)	log N	K
Binary Heap(PQ)	MN	لهما	NA	1	NA	AN
Unordered linked list	S	7	N	N	N	KN
ordered linked list (ascending)	7	N	N	1)	l	K
Ordered ST (BST)		(Sane a	s BST		
Unordered ST(hash table)				(NA)	NA	(NA)

 Algorithm 1 solves problems of size N by recursively dividing them into 3 subproblems of size N/3 and combining the results in time c (where c is some constant).

$$T(N) = (3.)T(N/3) + C = T(N) \neq O(N)$$

Algorithm 2 solves problems of size N by solving one sub-problem of size N/2 and performing some processing taking some constant time 1.

$$T(N) = T(N/2) + 1 \Rightarrow O(60N)$$

Algorithm 3 solves problems of size N by solving two sub-problems of size N/2 and performing a linear amount (i.e., cN where c is some constant) of extra work. $T(N) = 2T(N/2) + CN \longrightarrow T(N) \in N$

$$T(N) = T(N-1) + (N-1) + (N-1$$

Algorithm Analysis

- 1. What is the order of growth of the code above?
- 2. What is the number of array compares in tilde notation? $\sim \frac{1}{2}$

Amortized analysis

- Measure of average performance over a series of operations
 - Some good, few bad
 - Overall good (or not bad)
- Array resizing
 - Resize by 1 as extra space is needed
 - Resize by doubling the size as extra space is needed
 - Resize by tripling the size as extra space is needed

counting memory

- standard data types (int, bool, double)
- object overhead 16 bytes
- array overhead 24 bytes
- references 8 bytes
- Inner class reference 8 bytes (unless inner class is static)

```
private Node root;

private class Node {
    private int count;
    private Key key1, key2;
    private Value value1, value2;
    private Node left, middle, right; // the one or two values
}
...
```

public class TwoThreeTree<Key extends Comparable<Key>, Value> {

How much memory is needed for a 2-3 tree object that holds N nodes? Express the answer in tilde notation, big O notation

88N+8 Roof Overhand

Priority Queues

 Which operations are supported by a maxPQ? What is the worst case order of growth of each operation?

losN

What data structures can be used to implement a maxPQ?

bigheap, LL

What is the order invariant of a binary heap? What is a shape invariant?

Complete tree parent > Children

What is the minimum space requirement to implement a PQ?

tund [84)

PQ short questions

What is cost of finding a min in a maxPQ?

total wher

- What is the cost of finding a random key in a maxPQ?
- What is the cost of creating a sorted list using a minPQ?
- What is/are the major difference/s between a binary heap and a BST?

Hash Tables

- What are the two types of hashtables?
 - Linear probing and separate chaining
- How do we assure constant time performance of a hashtable?
 - Uniform hashing assumption
- What is the average length of a chain in a good hashtable?
 - See page 466 of the book. The average length grows with the function log N / log log N

2-3 trees and LLRB's

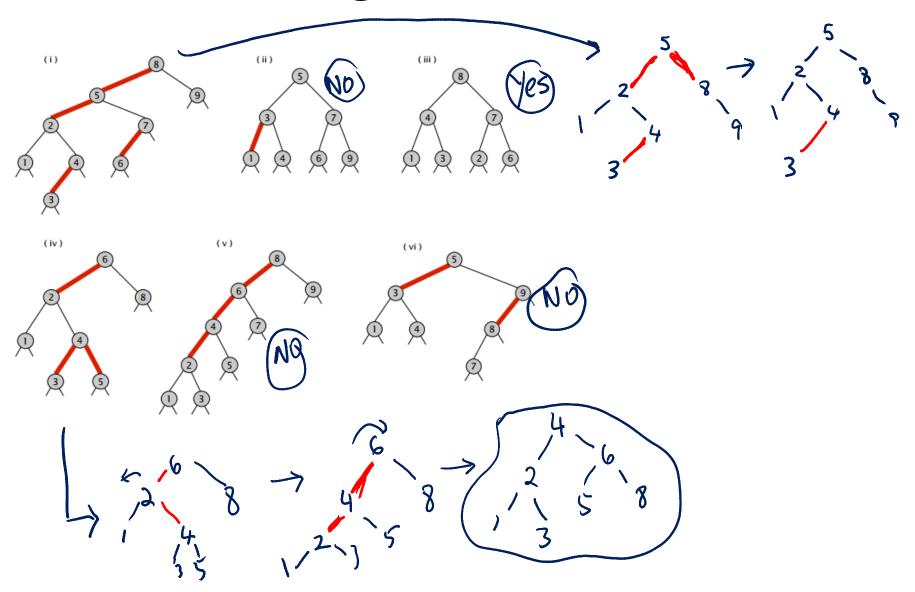

Insert 12, 8, 9, 10, 15, 17, 67 into a 2-3 tree

$$8910 \rightarrow 8912 \rightarrow$$

Show the corresponding LLRB

same as above. No red links.
All black links

Legal LLRB's?

Design Problems

Design problems

- Typically challenging
- There can be many possible solutions
 - partial credit awarded
- Usually it is a data structure design to meet certain performance requirements for a given set of operations
 - Example, create a data structure that meets the following performance requirements
 - findMedian in ~1 , insert ~ lg n, delete ~ lg n
 - Example: A leaky queue that can remove from any point, that can insert to end and delete from front, all in logarithmic time or better
- Typical cues to look for
 - log n operations are supported by sorted array or balanced BST or some sort of a heap
 - Constant time operations may indicate some use of a uniform hash table
 - Amortized time may indicate, you can have some costly operations once in a while, but on average, it must perform as expected

Guidelines

- Provide ONE clear solution
- Do not write essays
- Do not contradict your early arguments
- No need to write Java code (unless required).
 Just describe the idea clearly.
- Pay attention to performance requirements
- Pay attention to if you can use extra memory or not, and how much is allowed (constant, linear)

design problem #1

 Design a randomizedArray structure that can insert and delete a random Item from the array. Need to guarantee amortized constant performance

Kesizablu

- Insert(Item item)√
- delete()

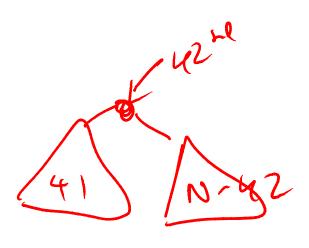

Design problem #2

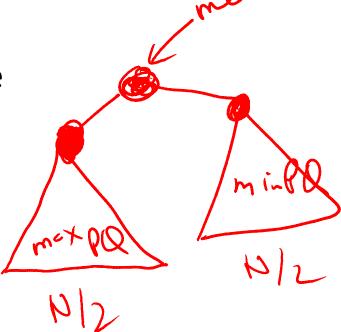

Design a data structure that can support the following operations

Insert(Comparable item) in log N

- delete() in log N

- findMedian in constant time

design problem #3

An ExtrinsicMaxPQ is a priority queue that allows the programmer to specify the priority of an object independent of the intrinsic properties of that object. This is unlike the MaxPQ from class, which assumed the objects were comparable and used the compare method to establish priority. You may assume the Items are comparable.

If an Item already exists in the priority queue, then its priority is changed instead of adding another item. All operations should complete in amortized logarithmic time in the worst case. Your ExtrinsicMaxPQ should use memory proportional to the number of items. For a small amount of partial credit, you may assume that no Item's priority is ever changed (i.e. no item is inserted twice).

```
Example:
                   // cat is inserted with priority 12
put("cat", 12)
put("dog", 10)
put("swimp is a raccoon who enjoys fries and does not like to eat dirt", 11)
put("dog", 15)
                   // dog's priority is changed to 15
                   // deletes dog, which has priority 15, cat is now max
delMax()
put("fish", 20)
                   // fish is inserted, and is now max
put("fish", 11)
                   // fish's priority is reduced to 11, cat is again max
delMax()
                   // removes cat (priority 12), either swimp or fish now max
                   // removing either swimp or fish is OK, both priority 11
delMax()
```

Design Problem #4

public class MoveToFront<Item>

MoveToFront()

create an empty move-to-front data structure

void add(Item item)

add the item at the front (index 0) of the sequence (thereby increasing the index of every other item)

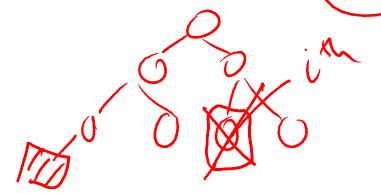

Item itemAtIndex(int i)

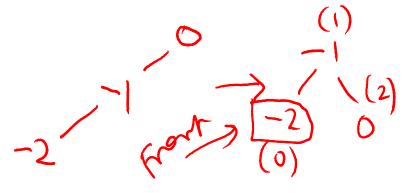

the item at index i

move the item at index i to index 0 (thereby increasing the index of items 0 through i-1)

All operations should take time proportional to $\log N$ in the worst case, where N is the number of items in the data structure.

Design problem #5

MIN-MAX Priority Queue

Standard priority queues come in two flavors: either a minimum priority queue (in which elements can be removed in descending order) or a maximum priority queue (in ascending order); and generally all operations can be implemented in logarithmic time.

Here, we would like to design a priority queue that allows for deletion, at any given time, either of the current minimum or the current maximum. In other words, the API should support the following operations:

Design an implementation in which all operations are supported in logarithmic worst-case time.

You can use a LLRB to implement the max-min PQ. Then the right most element (max) and left most element (min) can be deleted in log N time. Also inserts are log N. Binary heap implementation of PQ would not be a good choice in this case.

Design Problem #6

LRU cache.

An LRU cache is a data structures that stores up to N distinct keys. If the data structure is full when a key not already in the cache is added, the LRU cache first removes the key that was least recently cached.

Design a data structure that supports the following API:

			-	1 511 1/	
١	nuhl	10	class	LRU <key></key>	٠
ı	Pub		Cluss	LINUSINCY	

LRU(int N) create an empty LRU cache with capacity N if there are N keys in the cache and the given key is not already in the cache, (1) remove the key that void cache(Key key) was least recently used as an argument to cathe() and (ii) add the given key to the LRU cache is the key in the LRU cache? boolean inCache(Key key)

The operations cache() and inCache() should take constant time on average under the uniform hashing assumption.

Key choices for design problems

- Choice of data structure
 - LLRB
 - insert, delete, rank, update, find, max, min, rank (logarithmic time)
 - Hash table
 - insert, find, update (constant time with uniform hashing assumption)
 - Heap
 - delMax, insert (logarithmic)
 - symbol table
 - ordered (same as LLRB), unordered (same as hash table)
 - LIFO Stack and FIFO queue
 - inserts and deletes in amortized constant time with resizable array implementation

Possible/impossible questions

- We can build a heap in linear time. Is it possible to build a BST in linear time?
 - No. If it is possible then we would know a sorting algorithm that is less than N log N (lower bound for sorting)
- is it possible to find the max or min of any list in log N time?
 - No. unless something is known about the list (eg: sorted) it would not be possible to find max or min in less than linear time. You will have to inspect all elements
- Is it possible to create a collection where an item can be stored or found in constant time
 - SURE. We can use a hashtable
- Is it possible to design a max heap where find findMax, insert and delMax can be done in constant time?
 - NO. if so, we can do heapsort in linear time. Again violation of the sorting lower bounds (N log N)

Possible/impossible questions

 is it possible to implement a FIFO queue using a single array, still have amortized constant time for enque and deque?

Yes, we can use two stacks (enque, deque) to implement FIFO queue

 Is it possible to solve the 3-sum problem in n log n time?

This is an open problem. We know 3 ways of solving 3 sum

- 1. Naïve just check a[i], a[j], a[k] using 3 loops O(N^3)
- 2. Better Sort the array, for each pair (a[i], a[j]) binary search for a[k] = −(a[i] + a[j]) → O(N^2 log N)
- 3. Even better. Hash the a[i] into a table. for each pair (a[i], a[j]) search for a[k] = $-(a[i] + a[j]) \rightarrow O(N^2)$

Possible/impossible questions

- is it possible to sort a list of n keys in linear time, where only d (some small constant) distinct keys exists among n keys?
 - Yes, use a 3-way quicksort

- Is it possible to find median in an unsorted list in linear time?
 - Yes, use quickselect

Assignments

percolation

 What data structures were used to solve percolation problem?

What is the order of growth of percolateStat() method? Under what assumptions?

$$2N^{2}l_{0}N^{2} = N^{2}l_{0}gN^{2} \rightarrow Weighted UF$$

 $N^{4} = N^{2}.N^{2} \rightarrow Weighted UF$

Deque and Randomized Queue

 What data structures were used to implement a deque operations, addFirst etc

Linked List,

 What data structures were used to implement a randomized queue operations, enque, sample etc

Resizable Array

Autocomplete

 What data structures were used to implement autocomplete?

What were the key methods? What is the order of growth?

8-Puzzle

 What data structures were used to implement 8-puzzle?

What were the key methods? What is the order of growth?
