GEOMETRIC APPLICATIONS OF BSTs

- Warm-up: 1d range search
- line segment intersection
- $kd$ trees

https://algs4.cs.princeton.edu
Overview

This lecture. Intersections among geometric objects.

Applications. games, movies, virtual reality, databases, GIS, CAD, ....

Efficient solutions. Binary search trees (and extensions).
Overview

Courses that build on this lecture’s contents.

- COS 451: Computational geometry
- COS 426: Computer graphics

Medical imaging  Voronoi tessellation  fluid flow
GEOMETRIC APPLICATIONS OF BSTs

- Warm-up: 1d range search
- line segment intersection
- kd trees
Recall: ordered operations in symbol tables

1d range search

Extension of ordered symbol table.

- Insert key–value pair.
- Search for key \( k \).
- Delete key \( k \).
- **Range search:** find all keys between \( k_1 \) and \( k_2 \).
- **Range count:** number of keys between \( k_1 \) and \( k_2 \).

Geometric interpretation.

- Keys are point on a line.
- Find/count points in a given 1d interval.
Suppose that the keys are stored in a sorted array. What is the running time for range count as a function of $n$ and $R$?

A. $\log R$
B. $\log n$
C. $\log n + R$
D. $n + R$

$n = \text{number of keys}$
$R = \text{number of matching keys}$
1d range search: elementary implementations

Ordered array. Slow insert; fast range search.
Unordered list. Slow insert; slow range search.

order of growth of running time for 1d range search

<table>
<thead>
<tr>

<td>$n$</td>
<td>$n$</td>
</tr>
<tr>
<td>goal</td>
<td>$\log n$</td>
<td>$\log n$</td>
<td>$R + \log n$</td>
</tr>
</tbody>
</table>

$n =$ number of keys

$R =$ number of keys that match
1d range search: BST implementation

1d range search. Find all keys between lo and hi.
- Recursively find all keys in left subtree (if any could fall in range).
- Check key in current node.
- Recursively find all keys in right subtree (if any could fall in range).

Proposition. Running time proportional to $R + \log n$.
Pf. Nodes examined = search path to lo + search path to hi + matches.
1d range search: summary of performance

**Ordered array.** Slow insert; fast range search.

**Unordered list.** Slow insert; slow range search.

**BST.** Fast insert; fast range search/count.

*use rank() function*  

$n = \text{number of keys}$  

$R = \text{number of keys that match}$
GEOMETRIC APPLICATIONS OF BSTs

- Warm-up: 1d range search
- line segment intersection
- kd trees
Orthogonal line segment intersection

Given $n$ horizontal and vertical line segments, find all intersections.

Quadratic algorithm. Check all pairs of line segments for intersection.
Microprocessors and geometry

Microprocessor design involves geometric problems.

- Certain wires cannot intersect.
- Certain spacing needed between different types of wires.
- Debugging = line segment (or rectangle) intersection.
Non-degeneracy assumption. All $x$- and $y$-coordinates are distinct.

No overlapping horizontal lines or overlapping vertical lines (preprocess those separately).
Orthogonal line segment intersection: sweep-line algorithm

Sweep vertical line from left to right.  

- \( h \)-segment (left endpoint): insert \( y \)-coordinate into BST.

non-degeneracy assumption: all \( x \)- and \( y \)-coordinates are distinct  

x-coordinates define events.
Orthogonal line segment intersection: sweep-line algorithm

Sweep vertical line from left to right.

- $h$-segment (left endpoint): insert $y$-coordinate into BST.
- $h$-segment (right endpoint): remove $y$-coordinate from BST.

non-degeneracy assumption: all $x$- and $y$-coordinates are distinct
Orthogonal line segment intersection: sweep-line algorithm

Sweep vertical line from left to right.  \(x\)-coordinates define events.

- \(h\)-segment (left endpoint): insert \(y\)-coordinate into BST.
- \(h\)-segment (right endpoint): remove \(y\)-coordinate from BST.
- \(v\)-segment: range search for interval of \(y\)-endpoints.

non-degeneracy assumption: all \(x\)- and \(y\)-coordinates are distinct
Orthogonal line segment intersection: sweep-line analysis

**Proposition.** The sweep-line algorithm takes time proportional to $n \log n + R$ to find all $R$ intersections among $n$ orthogonal line segments.

**Pf.**
- Put $x$-coordinates on a PQ (or sort).
- Insert $y$-coordinates into BST.
- Delete $y$-coordinates from BST.
- Range searches in BST.

**Bottom line.** Sweep line reduces 2d orthogonal line segment intersection search to 1d range search.
The **sweep-line algorithm** is a key technique in computational geometry.

**Geometric intersection.**
- General line segment intersection.
- Axis-aligned rectangle intersection.
- ...

**More problems.**
- Andrew’s algorithm for convex hull.
- Fortune’s algorithm Voronoi diagram.
- Scanline algorithm for rendering computer graphics.
- ...

---

Sweep-line algorithm: context

The sweep-line algorithm is a key technique in computational geometry.
GEOMETRIC APPLICATIONS OF BSTs

- Warm-up: 1d range search
- line segment intersection
- *kd* trees
2-d orthogonal range search

Extension of ordered symbol-table to 2d keys.

- Insert a 2d key.
- Search for a 2d key.
- **Range search**: find all keys that lie in a 2d range.
- **Range count**: number of keys that lie in a 2d range.

**Applications.** Networking, circuit design, databases, ...

**Geometric interpretation.**

- Keys are point in the plane.
- Find/count points in a given \(h \times v\) rectangle
Space-partitioning trees

Use a tree to represent a recursive subdivision of 2d space.

**Grid.** Divide space uniformly into squares.

**Quadtree.** Recursively divide space into four quadrants.

**2d tree.** Recursively divide space into two halfplanes.

**BSP tree.** Recursively divide space into two regions.
Space-partitioning trees: applications

Applications.

- Ray tracing.
- 2d range search.
- Flight simulators.
- N-body simulation.
- Collision detection.
- Astronomical databases.
- Nearest neighbor search.
- Adaptive mesh generation.
- Accelerate rendering in Doom.
- Hidden surface removal and shadow casting.

![Grid](image1)
![Quadtree](image2)
![2d tree](image3)
![BSP tree](image4)
2d tree construction

Recursively partition plane into two halfplanes.
Where would point K be inserted in the 2d tree below?

A. Left child of G.
B. Left child of J.
C. Right child of J.
D. Right child of I.
Data structure. BST, but alternate using $x$- and $y$-coordinates as key.
- No need to store orientation in node
- Add an extra argument to recursive methods denoting odd or even level
2d tree demo: range search

**Goal.** Find all points in a query axis-aligned rectangle.
- Check if point in node lies in given rectangle.
- Recursively search left/bottom (if any could fall in rectangle).
- Recursively search right/top (if any could fall in rectangle).
**2d tree demo: range search**

**Goal.** Find all points in a query axis-aligned rectangle.

- Check if point in node lies in given rectangle.
- Recursively search left/bottom (if any could fall in rectangle).
- Recursively search right/top (if any could fall in rectangle).
Suppose we explore the right/top subtree before the left/bottom subtree in range search. What effect would it have on typical inputs?

A. Returns wrong answer.
B. Explores more nodes.
C. Both A and B.
D. Neither A nor B.
Range search in a 2d tree analysis (assuming tree is balanced)

**Typical case.** $R + \log n.$

**Worst case.** $R + \sqrt{n}.$

Easy to balance if all points given at once
Goal. Find closest point to query point.
2d tree demo: nearest neighbor

- Check distance from point in node to query point.
- Recursively search left/bottom (if it could contain a closer point).
- Recursively search right/top (if it could contain a closer point).
- Organize method so that it begins by searching for query point.

query point

nearest neighbor = E
Suppose we always explore the left/bottom subtree before the right/top subtree in nearest-neighbor search. What effect will it have on typical inputs?

A. Returns wrong answer.
B. Explores more nodes.
C. Both A and B.
D. Neither A nor B.
Which of the following is the worst case for nearest-neighbor search?

A. 

B. 

C. 

D.
Nearest neighbor search in a 2d tree analysis

**Typical case.** \( \log n \).

**Worst case (even if tree is balanced).** \( n \).
2d tree: nearest neighbor

**Exercise.** List the order in which nodes will be visited in a nearest-neighbor search for the given query point.

Nodes visited: A B H I C F D

Champion after visit: A A A A C F F
Kd tree. Recursively partition $k$-dimensional space into 2 halfspaces.

Implementation. BST, but cycle through dimensions ala 2d trees.

Efficient, simple data structure for processing $k$-dimensional data.

- Widely used.
- Adapts well to high-dimensional and clustered data.
Assignment no-credit bonus: flocking birds

Q. What “algorithm” do starlings, migrating geese, starlings, cranes, bait balls of fish, and flashing fireflies use to flock?

http://www.youtube.com/watch?v=XH-groCeKbE
Flocking boids

**Boids.** Three simple rules lead to complex emergent flocking behavior:

- **Flock centering:** point towards the center of mass of \textit{k-nearest} boids.
- **Direction matching:** update velocity towards the average of \textit{k-nearest} boids.
- **Collision avoidance:** among \textit{k-nearest} boids, point away from those that are too close.
N-body simulation

Goal. Simulate the motion of $n$ particles, mutually affected by gravity.

Brute force. For each pair of particles, compute force: $F = \frac{G m_1 m_2}{r^2}$

Running time. Time per step is $n^2$.

http://www.youtube.com/watch?v=ua7YlN4eL_w
Appel’s algorithm for n-body simulation

**Key idea.** Suppose particle is far, far away from cluster of particles.
- Treat cluster of particles as a single aggregate particle.
- Compute force between particle and *center of mass* of aggregate.
Appel’s algorithm for n-body simulation

- Build 3d-tree with \( n \) particles as nodes.
- Store center-of-mass of subtree in each node.
- To compute total force acting on a particle, traverse tree, but stop as soon as distance from particle to subdivision is sufficiently large.

Impact. Running time per step is \( n \log n \) \( \Rightarrow \) enables new research.
