

# MIMO III: Channel Capacity, Interference Alignment

---

**COS 463: *Wireless Networks***

Lecture 18

**Kyle Jamieson**

[Parts adapted from D. Tse]

# Today

---

1. **Interference Channel Capacity**
  - **Single-Antenna Context**
2. MIMO Channel Capacity
3. Interference Alignment

# Two-User Interference Channel

---

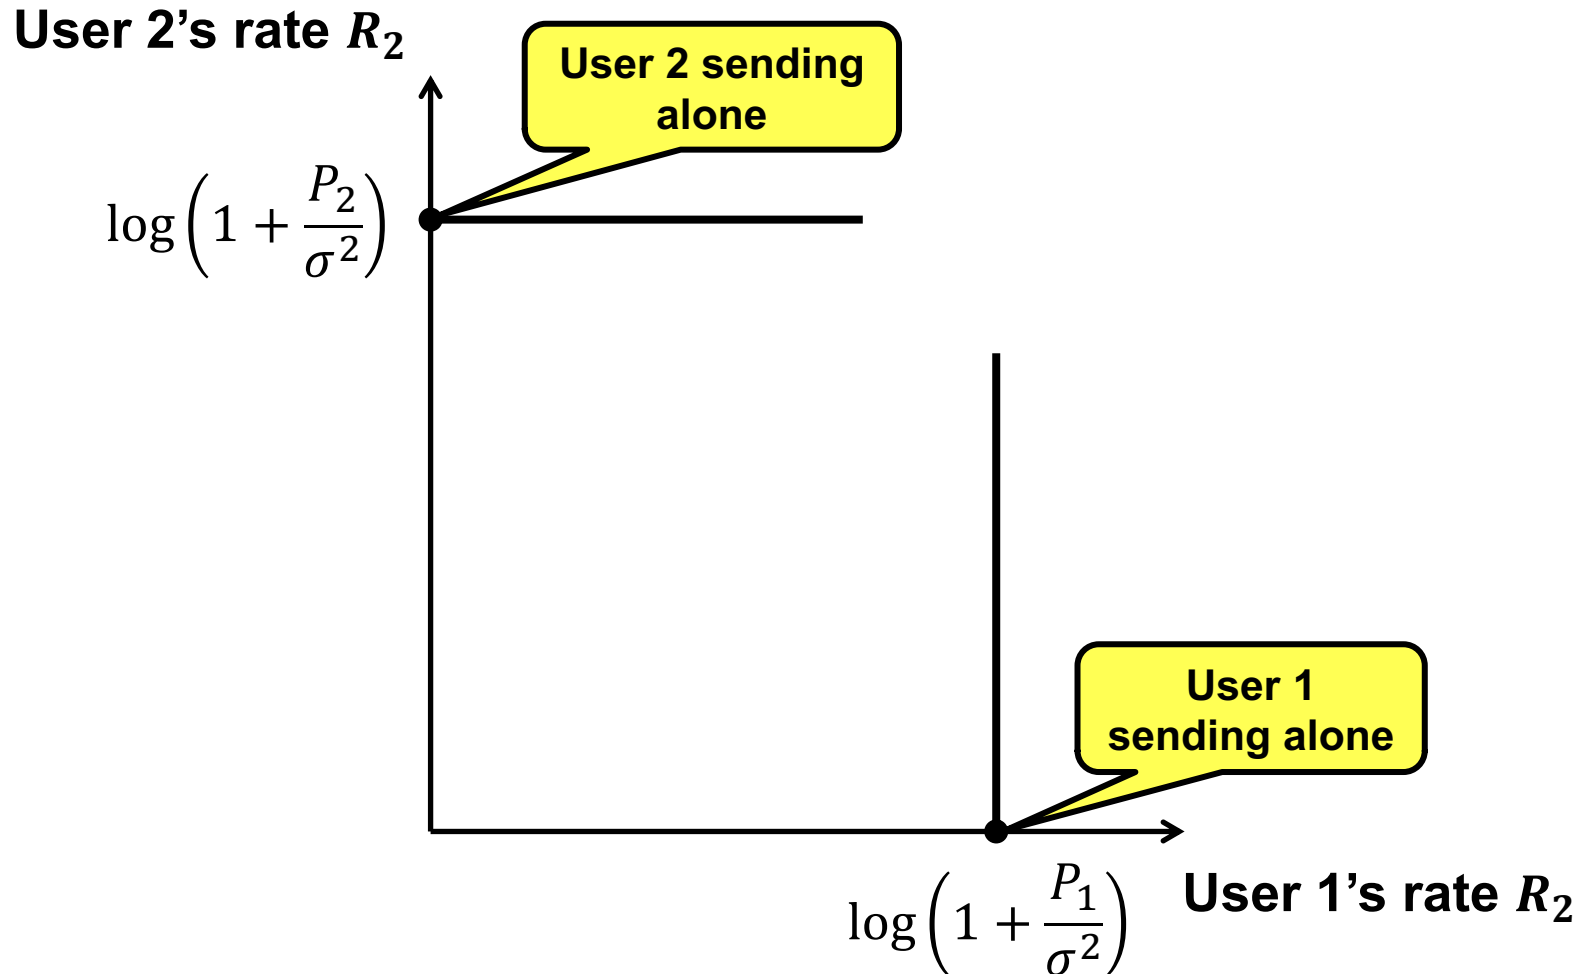

- On the **same frequency channel** at the **same time**:
  - **Sender 1** sends signal  $x_1$  with power  $P_1$
  - **Sender 2** sends signal  $x_2$  with power  $P_2$
- **AP receives:**  $y[m] = x_1[m] + x_2[m] + w[m]$ 
  - $w[m]$  is background Gaussian Noise with variance  $\sigma^2$
- **What are the fundamental limits of communication here?**

# Extension of Capacity to Multiple Users

---

- **Single-channel** Shannon capacity is a **single rate** (bits/s/Hz)
- Generalizing for two users **capacity** becomes a **region**:
  - Set of all pairs  $(R_1, R_2)$  such that **simultaneously**,
    - User 1 can reliably communicate at rate  $R_1$  **and**
    - User 2 can reliably communicate at rate  $R_2$
  - **Tradeoff between reliable communication rates**:
    - If **User 1** wants to **increase** its rate, **User 2** may need to **decrease** its rate

# Two-User Interference Channel: Single-User Bounds

# Interference Doesn't Help

---

- **Assumption:** User 1's data are completely independent from User 2's data, and vice-versa
- **Thought exercise:** Point-to-point link sending with power  $P_1 + P_2$ 
  - Must outperform interfering link (otherwise interference helps)
- So therefore,  $R_1 + R_2 < \log \left( 1 + \frac{P_1 + P_2}{\sigma^2} \right)$

# Two-User Interference Channel: Capacity Region

User 2's rate  $R_2$

# Successive Interference Cancellation (SIC)

---

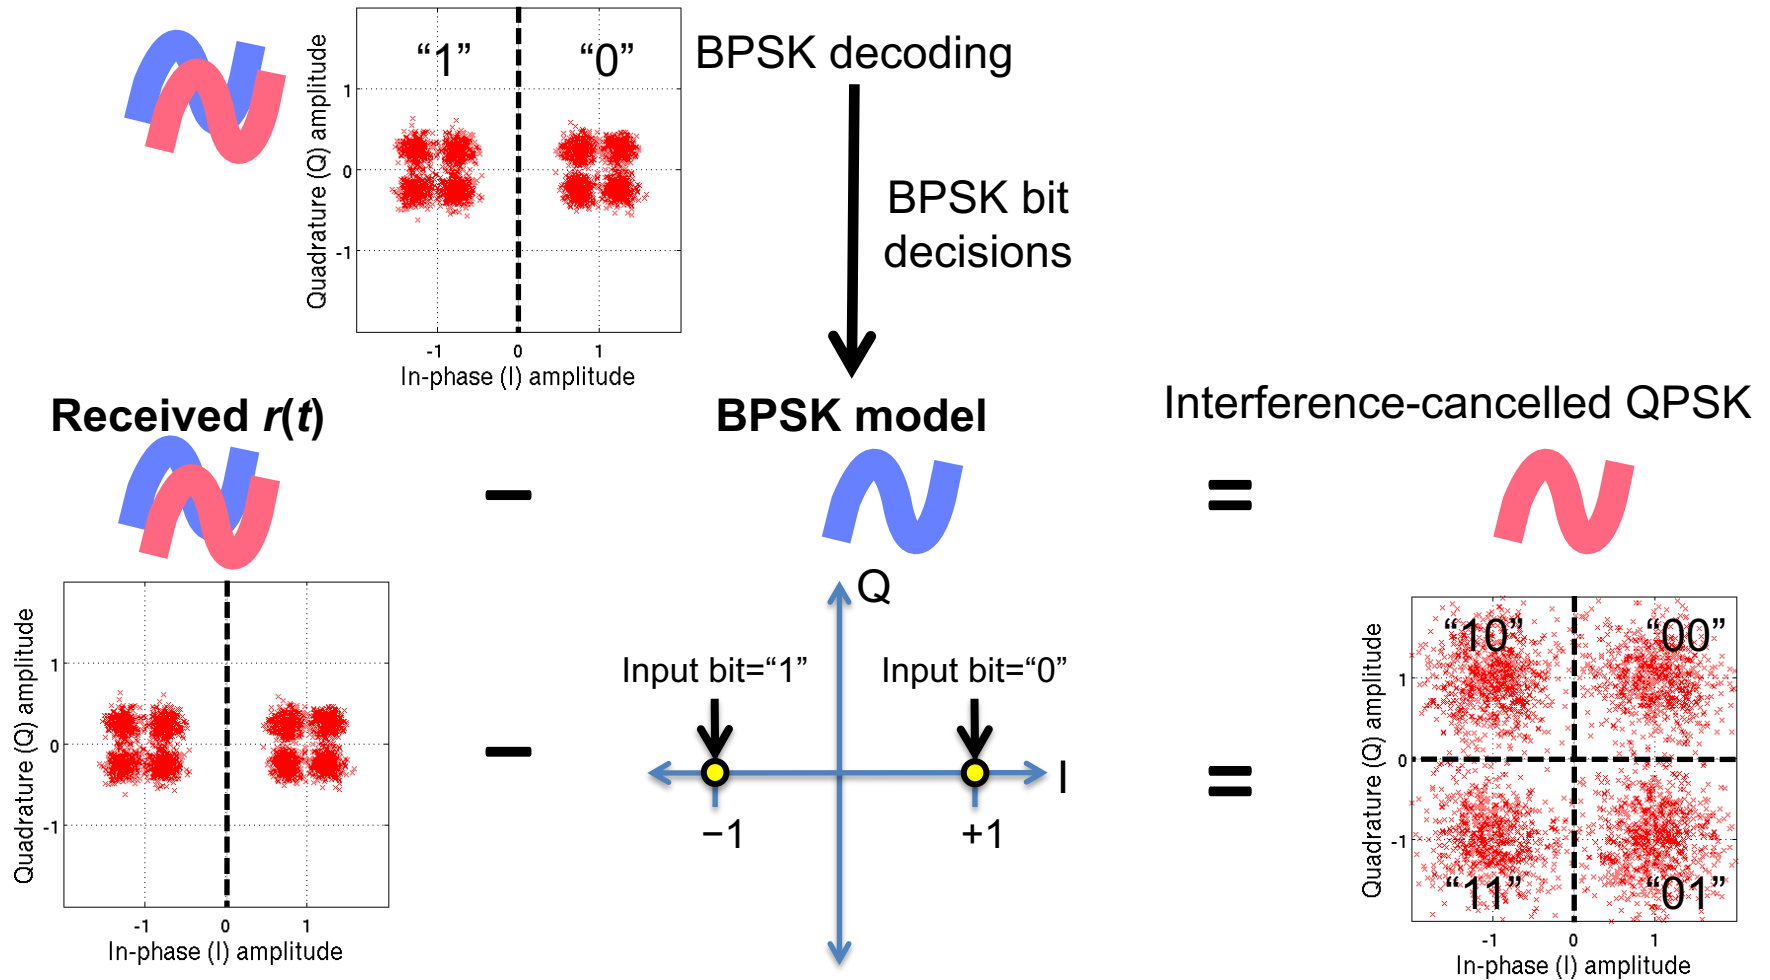

- Receiver decodes information **from both senders** in three stages:
  - Decode data of user 1, **treating signal from user 2 as noise**
  - Reconstruct **user 1's** signal ( $x'_1[m]$ ) from decoded data and **subtract from aggregate** received signal  $y[m]$ , **cancelling it:**

$$\begin{aligned}y'[m] &= y[m] - x'_1[m] \\ &= x_2[m] + (x_1[m] - x'_1[m]) + w[m]\end{aligned}$$

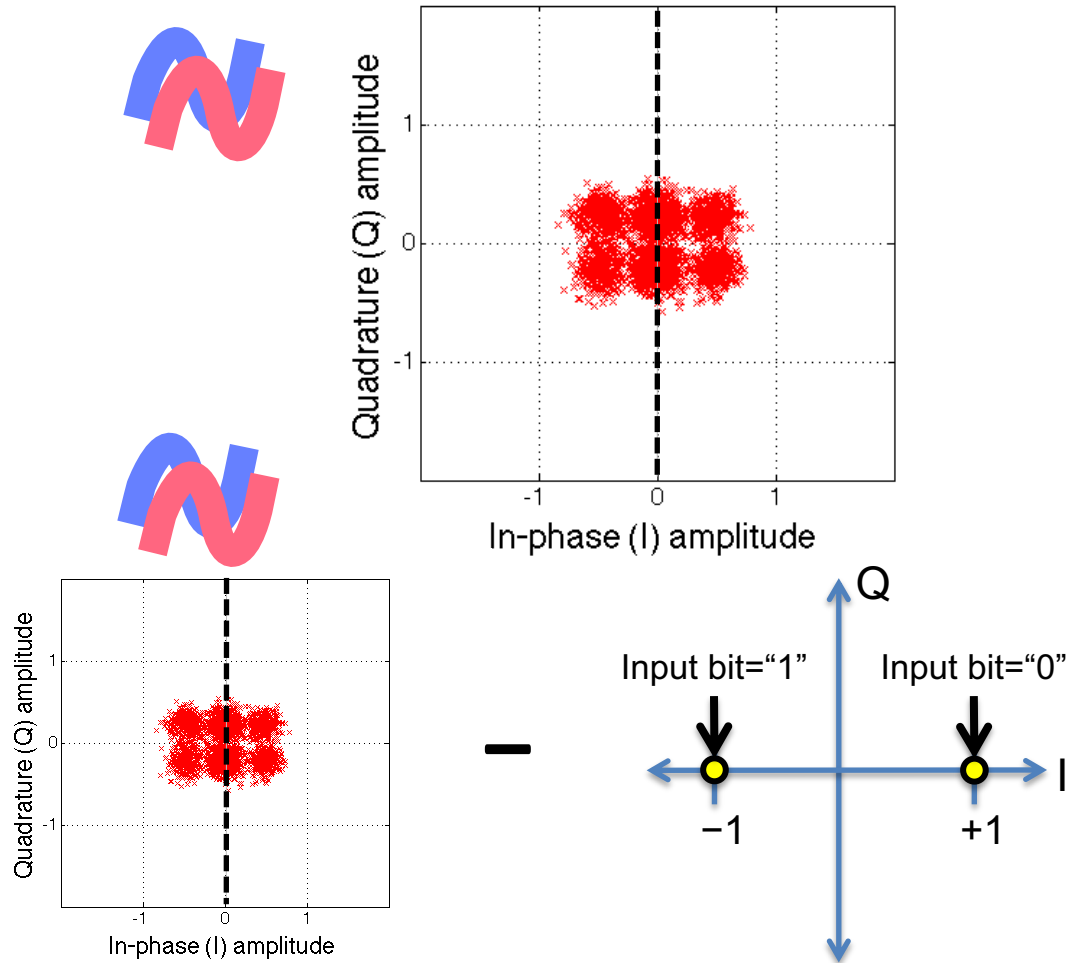

- Decode **user 2's** signal from  $y'[m]$

# Decoding Strong BPSK with weak QPSK

# Power Difference Helps Superposition Coding

# SIC: Choice of User Order

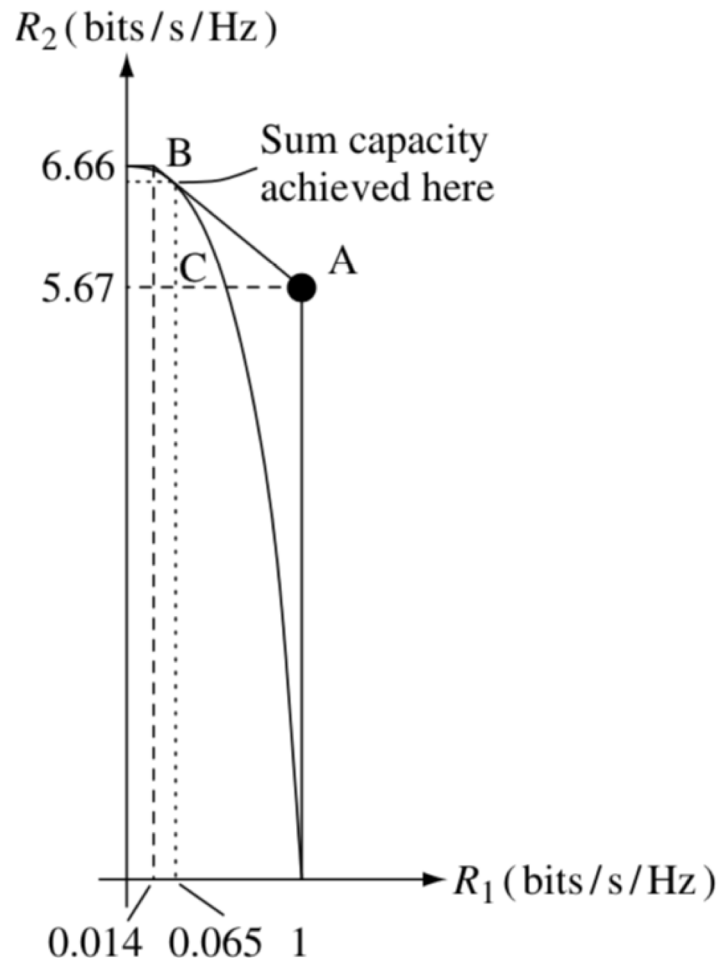

# Comparison with CDMA

- **CDMA:** Every user decoded treating the other users as noise
  - Achieves **Point C**
    - **But, User 1 starves**
- **CDMA power control:** Reduce power of the strong user
  - **Achieves Point D**

# Comparison with TDMA/FDMA + Power Control

- Allocate  $\alpha$  time- or frequency-fraction to User 1;  $1 - \alpha$  to User 2
- Scale each user's power according to allocated proportion

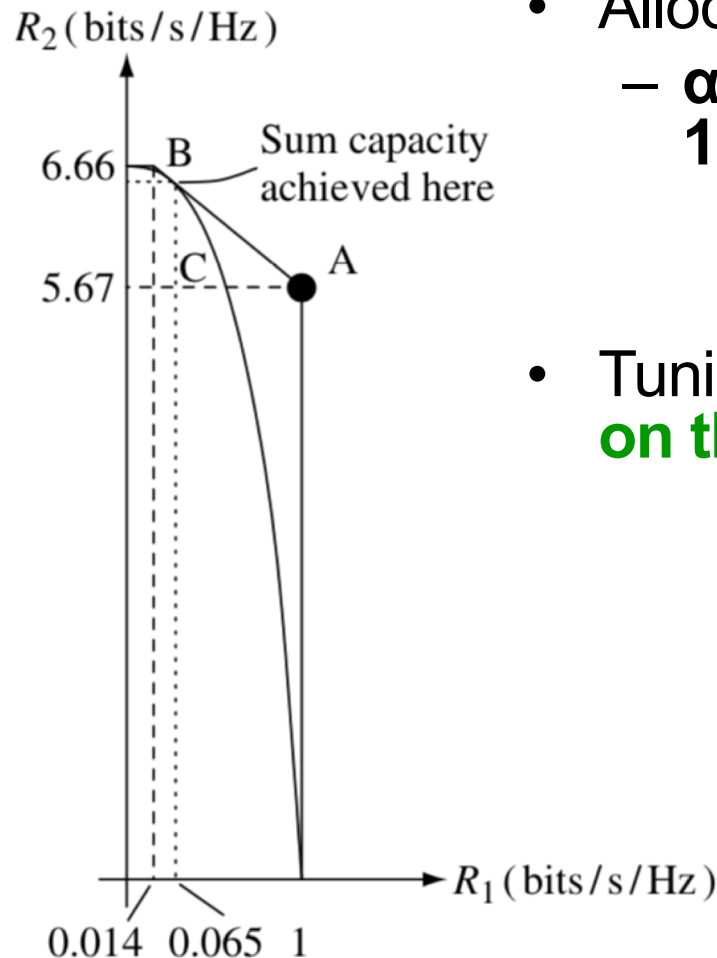

- User 1 maximum rate:

$$\alpha \log \left( 1 + \frac{P_1}{\alpha \sigma^2} \right)$$

- User 2 maximum rate:

$$(1 - \alpha) \log \left( 1 + \frac{P_2}{(1 - \alpha) \sigma^2} \right)$$

# Comparison with TDMA/FDMA + Power Control

- Allocate as follows:
  - $\alpha$  time- or frequency-fraction to **User 1**;  
 $1 - \alpha$  to **User 2**
- Tuning  $\alpha$ , the users **can achieve a point on the (optimal) A-B line**

# Today

---

1. Interference Channel Capacity

**2. MIMO Channel Capacity**

3. Interference Alignment

# Review: The MIMO Channel

- Transmit **three symbols** per symbol time:  $\vec{x} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}$
- Represent the MIMO channel as  $\vec{y} = \mathbf{H}\vec{x} + \vec{w}$ 
  - $\mathbf{H} = \begin{bmatrix} h_{11} & h_{12} & h_{13} \\ h_{21} & h_{22} & h_{23} \\ h_{31} & h_{32} & h_{33} \end{bmatrix}$  is the MIMO **channel matrix**,  $\vec{w}$  noise

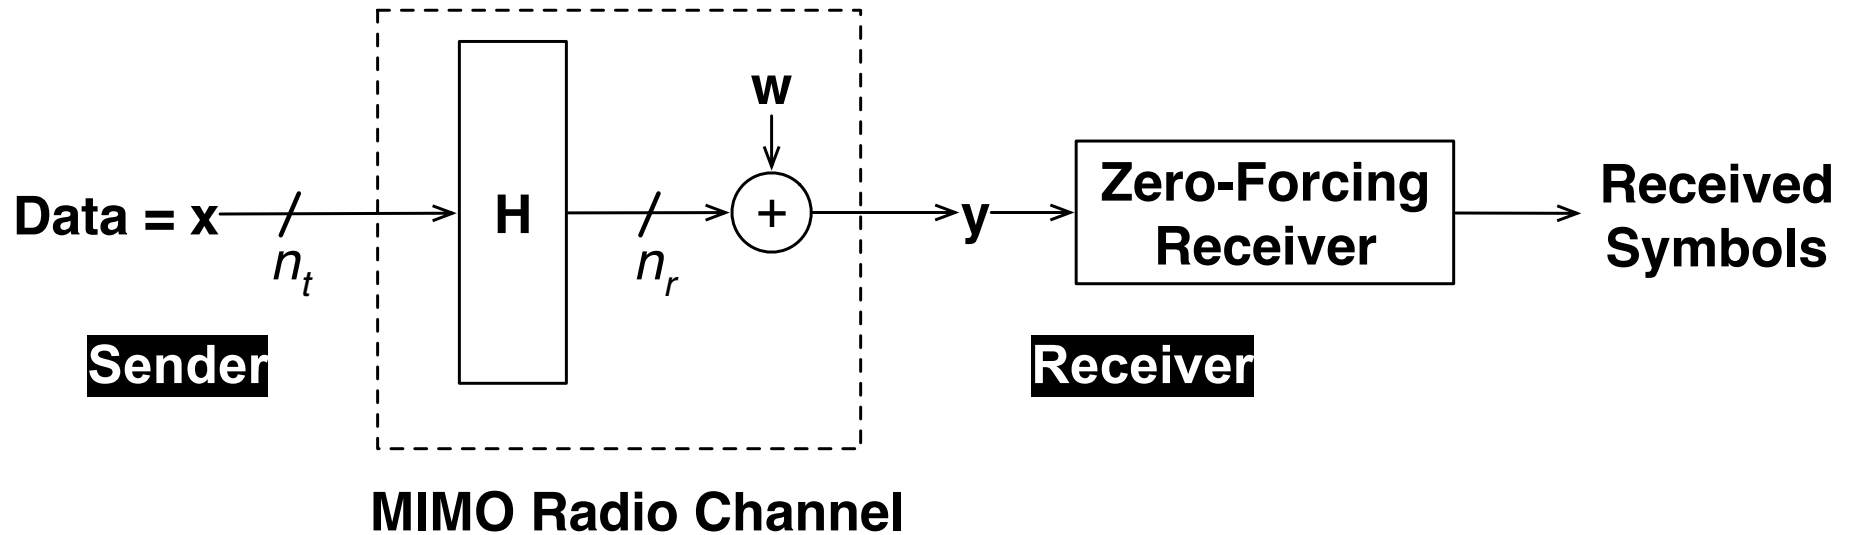

# Recap: MIMO Radio Channel

---

- MIMO **link** with  $n_t$  transmit,  $n_r$  receive antennas
- MIMO radio **channel itself:**

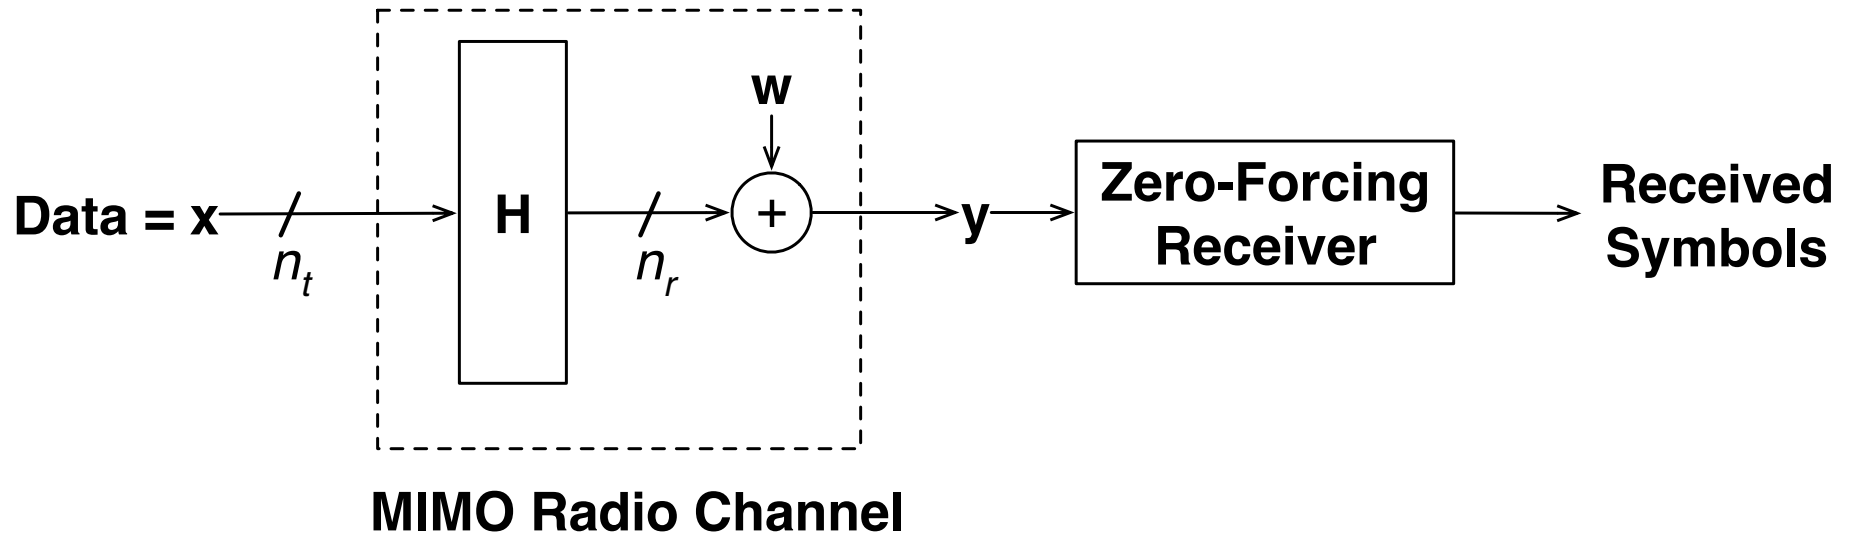

# Recap: Zero-Forcing MIMO

- **Transmitter** does not know **H** (channel)
- Each symbol time:
  - Sends  $n_t$  symbols (**original Data**), one per transmit antenna
- Data arrives **mixed together** at receiver antennas **y**

# Recap: Zero-Forcing MIMO

- **Receiver** knows **H** (channel)
- Each symbol time:
  - Receive  $n_r$  mixed-up signals **y**
  - **For each** of the  $n_t$  transmitted symbols:
    - Zero-Forcing Receiver **nulls all but that symbol**

# Today

---

1. Interference Channel Capacity

2. **MIMO Channel Capacity**

- **Vector Space Intuition**
- Eigenmode Forcing via Singular Value Decomposition

3. Interference Alignment

# MIMO Channel Capacity: Motivation

---

- The story so far: **Copy** data into  $\vec{x} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}$  each symbol time
  - Looked at when this performed **well, poorly**
    - Answer: **MIMO channel conditioning** ← “**Rich multipath environment**” around sender, receiver

\* \* \*

- Today's first topic: Is this the **best bits/seconds/Hz possible?**
  - *What's the capacity of a MIMO channel?*
    - Similar question: **Shannon capacity** of a single-input, single-output (**SISO**) channel

# Where's the Room for Improvement?

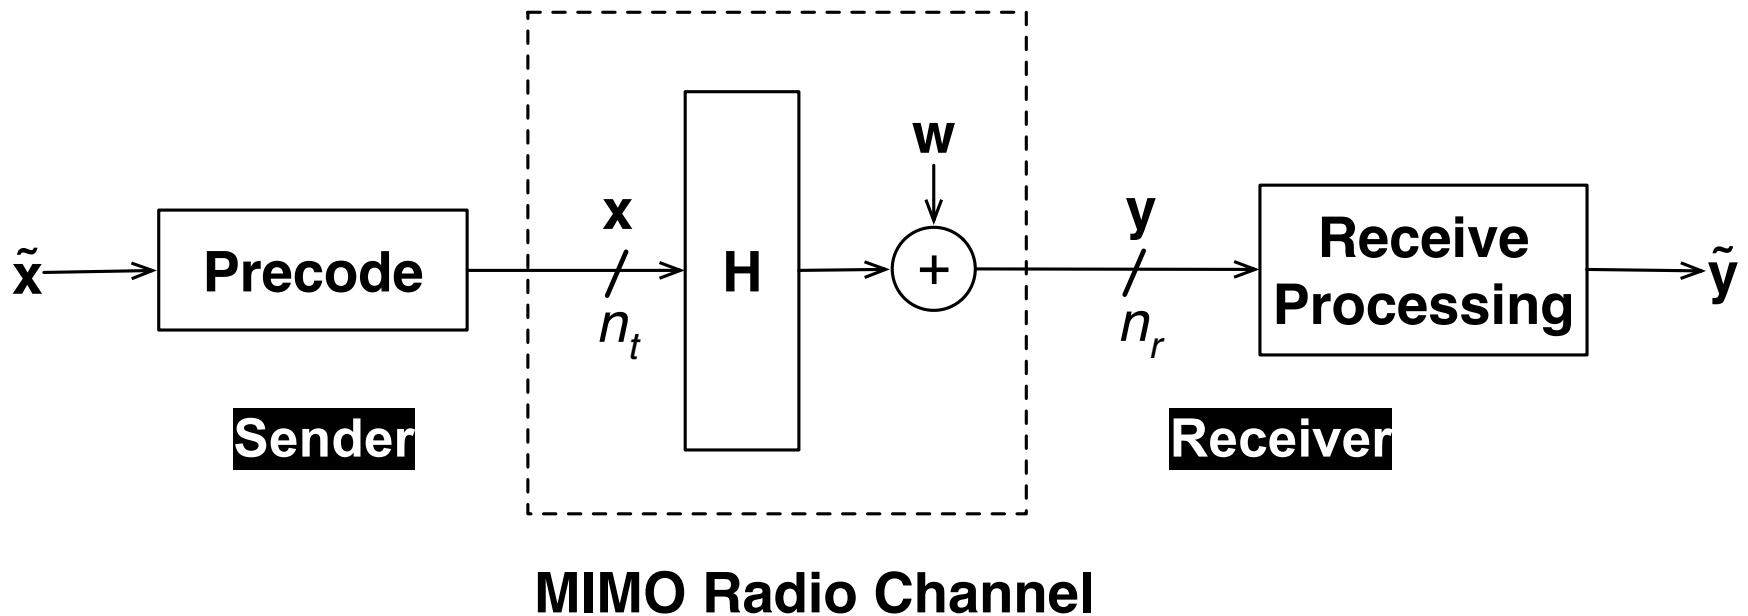

- Suppose the **transmitter knows**  $\mathbf{H}$  (channel)
- Zero-forcing receiver heard  $h_1, h_2, h_3$ 
  - **Power loss at receiver** (due to  $\text{Proj}_\perp$ ) for  $h_3$

- **Idea:** Use transmit antennas 2 and 3 to send the ideal direction
  - **No longer** simply **one symbol, one transmit antenna**

# How Might We Control Directions?

- Sender *precodes* data  $\tilde{\mathbf{x}}$  into **actual transmission in desired directions  $\mathbf{x}$**
- Receiver processing changes accordingly

# What Kind of Precoding?

---

- Recall, we wanted to make **independent channels** on each **wireless channel path**
- Suppose **H** were diagonal:

$$\mathbf{H} = \begin{bmatrix} \lambda_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \lambda_{n_t} \end{bmatrix}$$

- Then the  $\mathbf{y}_k$  channel output would only depend on  $\mathbf{x}_k$ 
  - **Parallel, independent channels**

# Today

---

1. Interference Channel Capacity

**2. MIMO Channel Capacity**

- Vector Space Intuition
- **Eigenmode Transmission**

3. Interference Alignment

# Singular Value Decomposition (SVD)

---

- The insight lies in a special way of “factoring” matrix  $\mathbf{H}$
- Any matrix  $\mathbf{H}$  has an SVD:  $\mathbf{H} \rightarrow \mathbf{U}\mathbf{\Lambda}\mathbf{V}^*$ 
  - $\mathbf{\Lambda}$  is a diagonal matrix (contains zeroes off-diagonal)
  - $\mathbf{U}$  and  $\mathbf{V}$  are *unitary* ( $\mathbf{U}\mathbf{U}^* = \mathbf{U}^*\mathbf{U} = \mathbf{V}\mathbf{V}^* = \mathbf{V}^*\mathbf{V} = \mathbf{I}$ )

# Interpreting the SVD Steps

- $\Lambda$  matrix with the  $m = \min(n_t, n_r)$  **singular values**  $\lambda_1, \dots, \lambda_m$ 
  - **One per** significant radio channel **path**
- $V^*$  **translates** to the **radio channel path coordinate system** where channels are decoupled
- $U$  **translates back**, to antenna coordinate system (undoes the  $V^*$  translation)

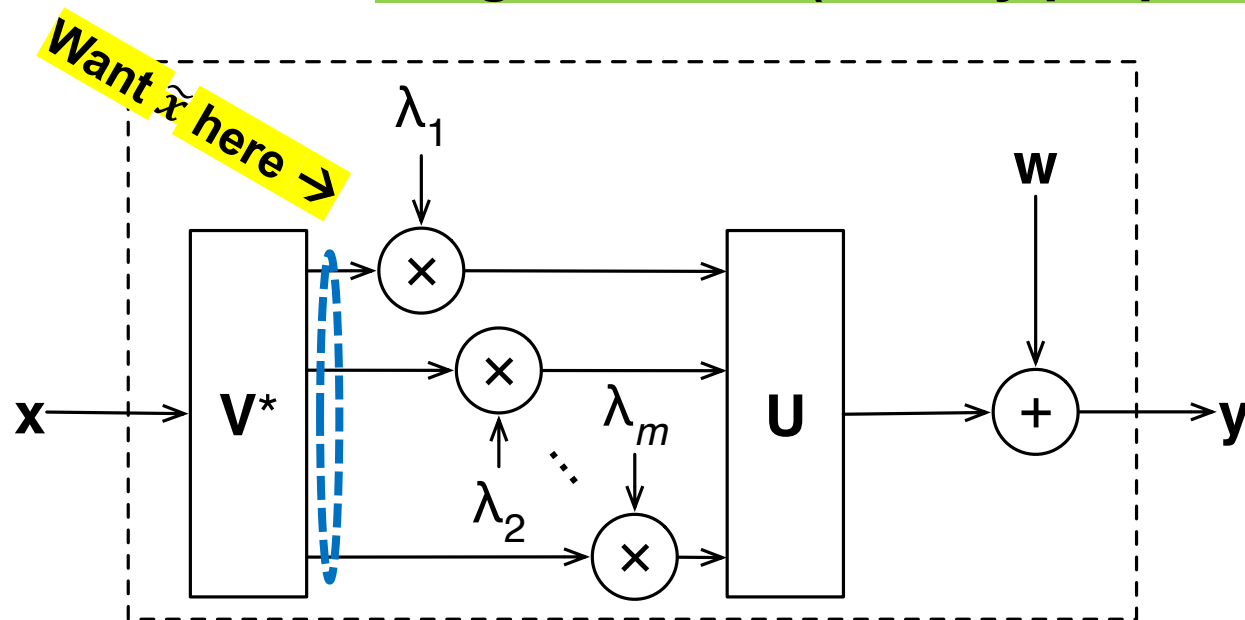

The diagram illustrates the SVD decomposition of the channel matrix  $H$ . It shows the equation  $H = U \Lambda V^*$  with dimensions indicated by curly braces. The matrix  $H$  is  $n_r \times n_t$ . The matrix  $U$  is  $n_r \times n_r$ . The matrix  $\Lambda$  is  $n_r \times n_t$ . The matrix  $V^*$  is  $n_t \times n_t$ . The dimensions are labeled as follows:  $n_t$  above  $H$ ,  $n_r$  to the left of  $H$ ,  $n_r$  above  $U$ ,  $n_r$  to the left of  $U$ ,  $n_r$  to the left of  $\Lambda$ ,  $n_t$  above  $\Lambda$ ,  $n_t$  above  $V^*$ , and  $n_t$  to the right of  $V^*$ .

$$\begin{matrix} n_t \\ \left. \begin{array}{|c|} \hline H \\ \hline \end{array} \right\} n_r \end{matrix} = \begin{matrix} n_r \\ \left. \begin{array}{|c|} \hline U \\ \hline \end{array} \right\} n_r \end{matrix} \times \begin{matrix} n_t \\ \left. \begin{array}{|c|} \hline \Lambda \\ \hline \end{array} \right\} n_r \end{matrix} \times \begin{matrix} n_t \\ \left. \begin{array}{|c|} \hline V^* \\ \hline \end{array} \right\} n_t \end{matrix}$$

# Leveraging the SVD in a Practical System

- **Alone, SVD does nothing** (just analyzes what  $\mathbf{H}$  does)
- Want to put data into the **radio channel coordinate system**

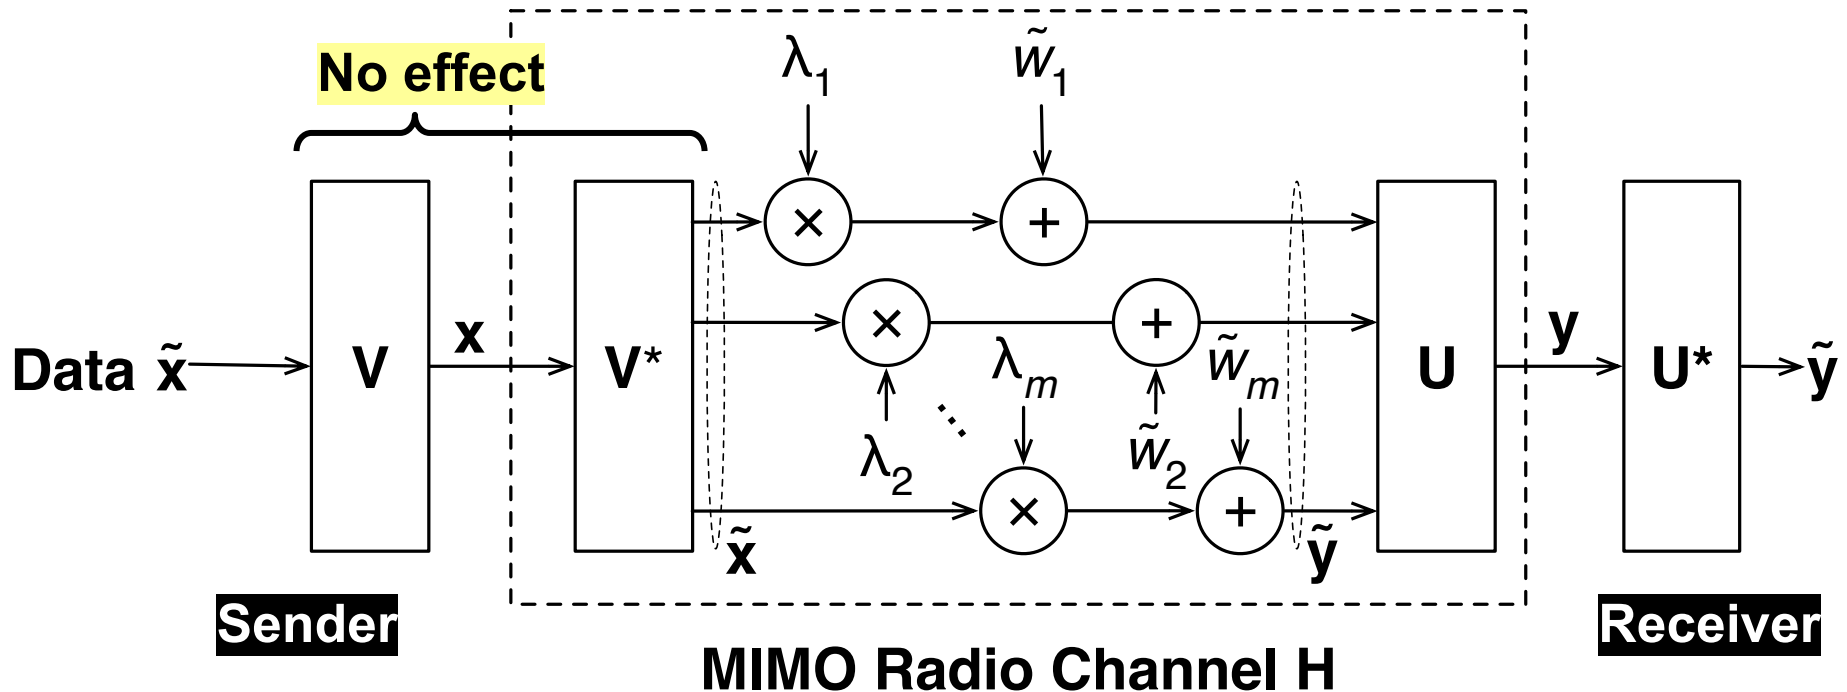

Insight:  $\mathbf{V}\mathbf{V}^* = \mathbf{I}$  (Unitary property)

**MIMO Radio Channel  $\mathbf{H}$**

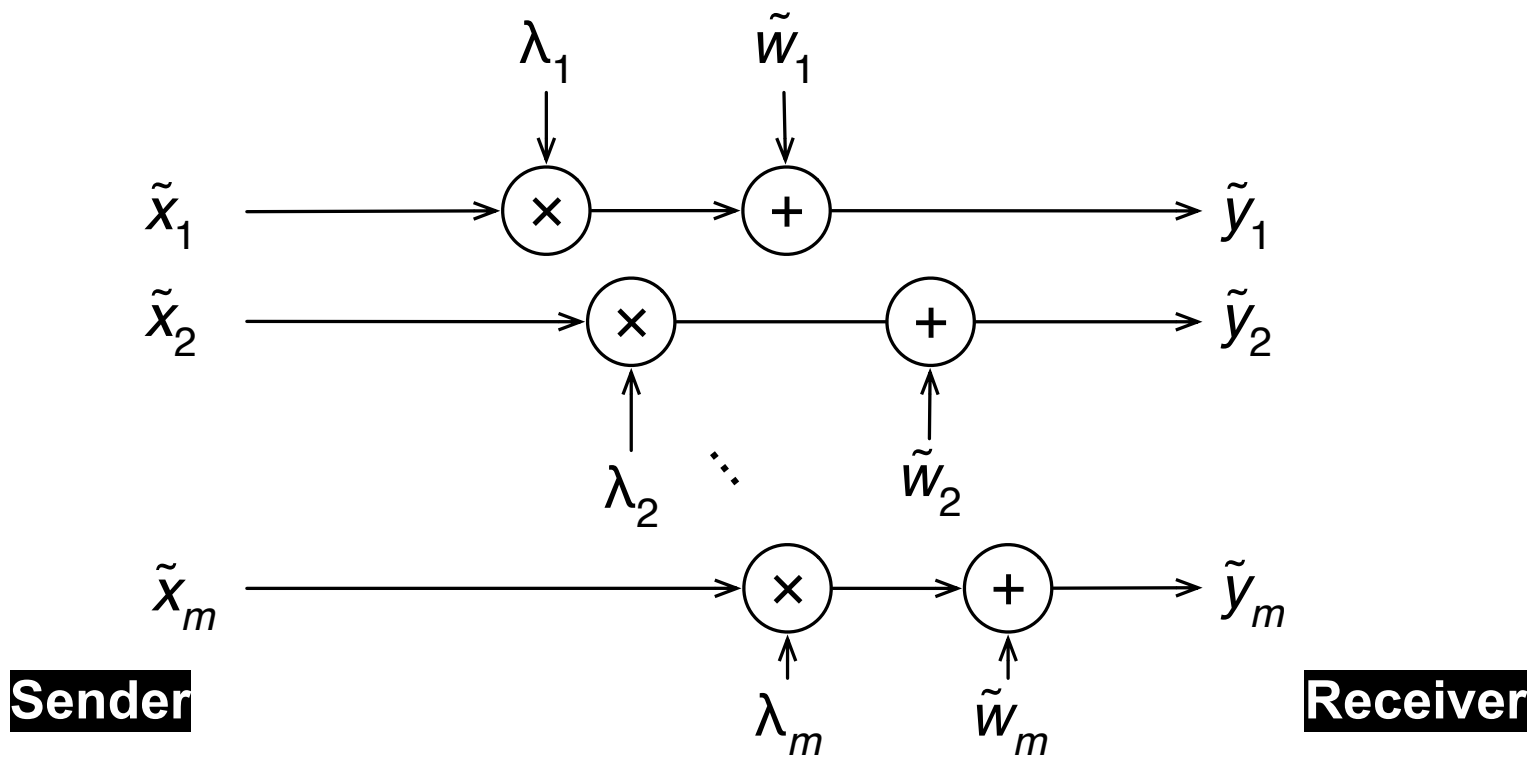

# Leveraging the SVD in a Practical System

- Sender precodes with  $\mathbf{V}$ , receiver “post-codes” with  $\mathbf{U}^*$ 
  - $\mathbf{V}$  is unitary, so  $\mathbf{V}^*\mathbf{V} = \mathbf{I}$  (same for  $\mathbf{U}$ )
    - So data sees **independent channels**
- This is called **MIMO eigenmode transmission**

# A Model for Eigenmode Transmission

- **Performance model** for the eigenmode transmitter/receiver
- All channels **decoupled**, transmit power  $P_k \rightarrow$  SNR on  $i^{\text{th}}$  channel:  $\frac{P_i \lambda_i^2}{\sigma^2}$

# Performance: Uniform Power Division

---

- At high SNR (the common case in wireless LANs), with ***total transmit power***  $P$  **evenly divided over spatial paths**

- Data rate =  $\sum_{i=1}^k \log \left( 1 + \frac{P\lambda_i^2}{kN_0} \right) \approx k \log(\text{SNR})$

\* \* \*

- *How can we do better?*
  - **Idea:** Allocate **different transmit powers**  $P_i$  to different radio channel paths  $i$
  - Problem we've **seen before in 463** in **OFDM context**

# Waterfilling for MIMO Power Allocation

Allocated transmit  
power  $P_i$

# MIMO Capacity: Takeaways

---

- OFDM – MIMO analogy:

A **transformation** (**OFDM: FFT**, **MIMO: SVD**)  
renders **interfering channels** in  
(**OFDM: frequency**, **MIMO: space**) **independent**

- MIMO Eigenmode transmission:

- Transmitter **sends directionally**, along spatial paths of the radio channel
- Receiver **listens directionally**, along same spatial paths
- Achieves the **MIMO channel capacity**

# Today

---

1. Interference Channel Capacity
2. MIMO Channel Capacity
- 3. Interference Alignment**

# Interference Alignment (IA)

---

- **Number of concurrent MIMO streams** a client can send is **limited by the number of antennas**
  - Sending more streams results in **interference between streams**
  - Also limited by the amount of multipath in the environment
- **New Idea:** Use MIMO precoding techniques to **align interference** at receivers to advantage
- Requires APs **cooperating via a wired backhaul**
  - e.g. APs owned by one organization

# MIMO channel representation

- As before, model channel from one antenna  $i$  to another  $j$  as one complex number  $h_{ij}$
- Channel matrix  $\mathbf{H}$  from a client to an AP is formed by  $[h_{ij}]$

# Uplink: Interference Between Networks

- **Client 1 has 2 packets for AP 1; Client 2 has a packet for AP 2**
  - Two-antenna APs, so each decoding in a 2-D space
- Three packets form three vectors in the 2-D space at each AP
  - **Therefore, the APs can't decode these 3 packets**

# Interference alignment: Basic idea (1)

---

1. Clients transmit  $p_2$  and  $p_3$  **aligned** at access point (AP) 1
  - They **add up** in their one direction
2. AP 1 **zero-forces to decode  $p_1$** , sends it **over backhaul to AP 2**
3. AP 2 subtracts  $p_1$  from the signal it receives, **cancelling it**

# Interference alignment: Basic idea (2)

---

4. AP **2** uses zero-forcing receiver to **decode**  $p_2, p_3$
5. AP **2** sends  $p_2$  to AP **1** (or onward on behalf of client **1**)

# Uplink: Sketching a Practical Protocol

- Transmit precoding: client multiplies packet by **vector**  $v$ 
  - **Changes alignment at receiver**

1. **Client 1** picks **random** precoding vectors  $v_1$  and  $v_2$
2. **Client 1** begins transmission

3. **Client 2** chooses  $v_3$  so that  $\mathbf{H}_{11}v_2 = \mathbf{H}_{21}v_3$ 
  - *How does client 2 know  $\mathbf{H}_{11}$  and  $\mathbf{H}_{21}$ ?*
    - Client 1 can **include in its packet header**

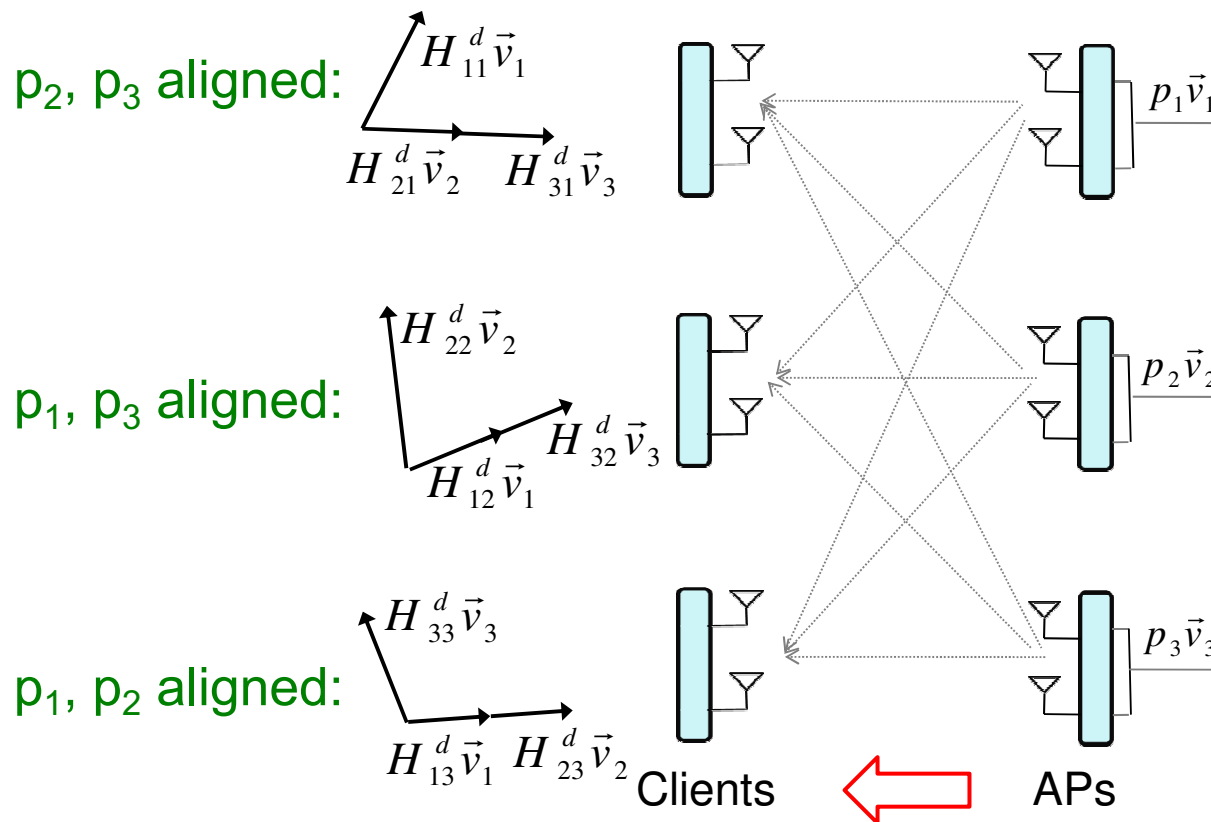

# Uplink: Four Concurrent Packets?

- All packets but one ( $p_1$ ) must align at AP 1, so AP 1 can decode
- Subtract  $p_1$  from the four packets at AP 2, leaving three packets
- AP 2 can only decode two packets at a time (2-d space)
  - **Can't decode  $p_3$  and  $p_4$  at AP 2: Can only decode  $p_1$  and  $p_2$**

# Downlink Interference Alignment

- Clients **can't exchange frames over backhaul**
- Instead, **align neighboring APs' interference** at each client

**Thursday Topic:**  
**Ripple II: Faster Communication  
through Physical Vibration**

**(Download & Pre-read paper!)**
