

Program Design

1. Problem statement and requirements:

What is the problem?

2. Specification:

Detailed description of what the system does instead of how.

3. Design:

Explore design space (like “back of the envelope” calculations), identify algorithms and key interfaces

4. Programming:

Implement it in the simplest possible way; use libraries

5. Testing:

Debug and test until the implementation is correct

6. Iterate:

Do the design and implementation conform to the specification?

Stepwise Refinement

- Top-down design
 - starts with a **high-level abstract** solution
 - refines** it repeatedly by successive transformations to lower-level solutions
 - refinement ends at programming language statements
- Key idea: each refinement or **elaboration**
 - must be **small, and correct**
 - must move toward final solution
- Accompany refinements with **assertions** to help ensure **correctness**
- Refinements use English and pseudocode, but ultimately result in **code**:

Example: How Many Library Books are Never Used?

1. Problem statement:

The circulation file has a line of author& title for each checked out book.

Need a program to answer how many books circulate in a year

2. Specification:

`unique` reads its standard input and prints the number of distinct (non-redundant) lines on the standard output

3. Design: how many unique lines are in a typical circulation file?

top-down design

`<unique>` ≡

`<for each line of input>`

`<add the line to the set of strings>`

`<count how many lines are in the set>`

`<print the output>`

“chunks” are pseudocode to be elaborated

4. Programming: make forward progress by elaborating chunks

`<count how many lines in the set>` ≡

`count = 0;`

`<for each element of the set>`

`count++;`

What Modules?

- ADTs: sets of strings

- Modules:

`main.c` handle command-line arguments (if any) and top-level loops

`<unique>` ≡

`<includes>`

`<defines>`

```
int main(int argc, char *argv[]) {
```

`<locals>`

`<for each line of input>`

`<add the line to the set of strings>`

`<count how many lines are in the set>`

`<print the output>`

```
return EXIT_SUCCESS;
```

```
}
```

`strset.h` interface for sets of strings

`strset.c` initial implementation of sets of strings

- Use RCS to track changes

`main.c,v`

`strset.h,v`

`strset.c,v`

Elaboration

- Do the easy chunks first

<print the output> ≡
 printf("%d\n", count);

<locals> ≡
 int count = 0;

<includes> ≡
 #include <stdio.h>

- Some elaborations can be done without defining the ADTs

<for each line in the input> ≡
 while (gets(line))

<defines> ≡
 #define MAXLINE 512

<locals> +≡
 char line[MAXLINE];

indicates that code is appended to the chunk

ADT: Sets of Strings

`strset.h` describes ***abstract*** operations, ***not*** implementation; ***what***, not ***how***

```

#ifndef STRSET_INCLUDED
#define STRSET_INCLUDED

#define T Strset_T ← naming convention: ugly, but avoids name collisions
typedef struct T *T; ← opaque pointer type; clients can't see innards

T Strset_new(void);          /* allocates and returns a new, empty set */

void Strset_free(T *set);
    /* deallocates *set and its contents, set *set to NULL */

void Strset_add(T set, char *str);
    /* adds str to set, if str is not already in set */

void Strset_delete(T set, char *str);
    /* removes str from set, if str is in set */

int Strset_member(T set, char *str);
    /* returns 1 if str is in set, else 0 */

void Strset_foreach(T set, void apply(char *str, void *cl), void *cl);
    /* executes apply(s, cl) for each string s in set */

/* It is a checked runtime error to pass a NULL T, *T, char*, or apply
to any function in this interface. */

#undef T ← client responsibilities
#endif

```

Elaboration, cont'd

- ADT interface gives enough information to finish the client, `main.c`

<locals> +=

```
Strset_T set = Strset_new();
```

<includes> +=

```
#include "strset.h"
```

<add the line to the set of strings> ≡

```
Strset_add(set, line);
```

<count how many lines are in the set > ≡

```
Strset_foreach(set, cardinality, &count);
```

```
static void cardinality(char *str, void *cl) {
    int *p = cl;

    (*p)++;      /* or *(int *)cl++; */
}

```

- Implement clients of ADTs ***before*** the ADTs themselves; helps ***expose*** design ***inadequacies***

Strset

- Initial implementation can be simple; it might suffice ...
- Implementation reveals the innards of the opaque type: a list of strings

```
#include "strset.h"
#define T Strset_T

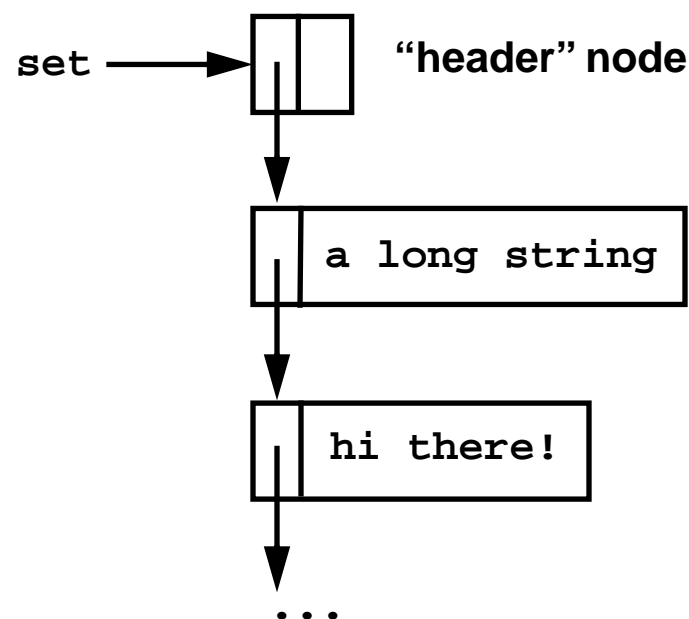

struct T {
    T next;
    char str[1];
};
```

- `strset_new` allocates a new header node

```
T Strset_new(void) {
    T set = calloc(1, sizeof *set);

    assert(set);
    return set;
}
```

OK during development and in COS 217, but not in production programs

Initial Implementation of Strset

- For now, implement only enough of the ADT to test `unique`

```

void Strset_add(T set, char *str) {
    T p = set;

    assert(set);
    assert(str);
    while ((p = p->next) != NULL)
        if (strcmp(str, p->str) == 0)
            return;
    p = malloc(sizeof *p + strlen(str));
    assert(p);
    strcpy(p->str, str);
    p->next = set->next;
    set->next = p;
}

void Strset_foreach(T set, void apply(char *str, void *cl),
void *cl) {
    assert(set);
    assert(apply);
    while ((set = set->next) != NULL)
        apply(set->str, cl);
}

```

Testing

5. Testing: `unique` works, but runs too slowly on *large* inputs; why?

improve `strset`'s implementation; don't change its interface

- Solution: use a *hash table* to represent a set of strings

a set is a pointer to an array of `TABLESIZE` linked lists

crunch the string into an integer `h`

let `i = h % TABLESIZE`

search the `i`th linked list for the string, or
add the string to the head of the `i`th list

Better Implementation of Strset

```

#include <assert.h>
#include <stdlib.h>
#include <string.h>
#include "strset.h"
#define T Strset_T

#define TABLESIZE 97
struct T {
    struct elem {
        struct elem *next;
        char str[1];
    } *table[TABLESIZE];
};

void Strset_free(T *set) {
    int i;

    assert(set && *set);
    for (i = 0; i < TABLESIZE; i++) {
        struct elem *p, *q;
        for (p = (*set)->table[i]; p; p = q) {
            q = p->next;
            free(p);
        }
    }
    free(*set);
    *set = NULL;
}

same as above!
T Strset_new(void) {
    T set = calloc(1, sizeof *set);

    assert(set);
    return set;
}

```

Better Implementation of Strset, cont'd

```
static unsigned hash(char *str) {
    unsigned h = 0;

    while (*str)
        h = (h<<1) + *str++;
    return h;
}

void Strset_add(T set, char *str) {
    int i;
    struct elem *p;

    assert(set);
    assert(str);
    i = hash(str)%TABLESIZE;
    for (p = set->table[i]; p; p = p->next)
        if (strcmp(str, p->str) == 0)
            return;
    p = malloc(sizeof *p + strlen(str));
    assert(p);
    strcpy(p->str, str);
    p->next = set->table[i];
    set->table[i] = p;
}
```

Better Implementation of Strset, cont'd

```
void Strset_foreach(T set, void apply(char *str, void *cl),
void *cl) {
    int i;

    assert(set);
    assert(apply);
    for (i = 0; i < TABLESIZE; i++) {
        struct elem *p;
        for (p = set->table[i]; p; p = p->next)
            apply(p->str, cl);
    }
}
```

- see files in `src/{strset,unique}`; RCS files track all improvements

More Testing

- **More** testing

test on “typical” inputs

test on **extreme** inputs:

a file with blank lines

a very long file

a long file with lines that are all identical

a file with very long lines

an empty file

...

- Very long lines causes `unique` to crash!

```
<for each line in the input> ≡  
while (gets(line))
```

`gets` can't check length of `line`

6. Iterate

go to step 2, amend the **specification**:

“Only the first 511 characters of a line are significant”

go to step 4 (programming) and fix the error (use RCS)

go to step 5 (testing) and repeat **all** of the tests

iterate again.
