

O'Caml Datatypes

COS 326

David Walker

Princeton University

O'CamI So Far

- We have seen a number of basic types:
 - int
 - float
 - char
 - string
 - bool
- We have seen a few structured types:
 - pairs
 - tuples
 - options
 - lists
- In this lecture, we will see some more general ways to define our own new types and data structures

Type Abbreviations

- We have already seen some type abbreviations:

```
type point = float * float
```

Type Abbreviations

- We have already seen some type abbreviations:

```
type point = float * float
```

- These abbreviations can be helpful documentation:

```
let distance (p1:point) (p2:point) : float =  
  let square x = x *. x in  
  let (x1,y1) = p1 in  
  let (x2,y2) = p2 in  
  sqrt (square (x2 -. x1) +. square (y2 -. y1))
```

- But they add nothing of *substance* to the language
 - they are *equal* in every way to an existing type

Type Abbreviations

- We have already seen some type abbreviations:

```
type point = float * float
```

- As far as O'Caml is concerned, you could have written:

```
let distance (p1:float*float)
             (p2:float*float) : float =
  let square x = x *. x in
  let (x1,y1) = p1 in
  let (x2,y2) = p2 in
  sqrt (square (x2 -. x1) +. square (y2 -. y1))
```

- Since the types are equal, you can substitute the definition for the name wherever you want
 - we have not added any new data structures

DATA TYPES

Data types

- O'CamL provides a general mechanism called a **data type** for defining new data structures that consist of many alternatives

```
type my_bool = Tru | Fal
```

a **value** with type **my_bool**
is one of two things:

- **Tru**, or
- **Fal**

read the "|" as "or"

Data types

- O'CamL provides a general mechanism called a **data type** for defining new data structures that consist of many alternatives

```
type my_bool = Tru | Fal
```

Tru and Fal are called
"constructors"

a **value** with type **my_bool**
is one of two things:

- **Tru**, or
- **Fal**

read the "|" as "or"

Data types

- O'CamL provides a general mechanism called a **data type** for defining new data structures that consist of many alternatives

```
type my_bool = Tru | Fal
```

```
type color = Blue | Yellow | Green | Red
```

there's no need to stop
at 2 cases; define as many
alternatives as you want

Data types

- O'CamL provides a general mechanism called a **data type** for defining new data structures that consist of many alternatives

```
type my_bool = Tru | Fal
```

```
type color = Blue | Yellow | Green | Red
```

- Creating values:

```
let b1 : my_bool = Tru  
let b2 : my_bool = Fal  
let c1 : color = Yellow  
let c2 : color = Red
```

use constructors to create values

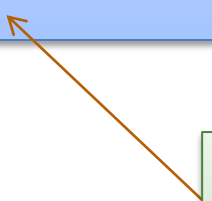

Data types

```
type color = Blue | Yellow | Green | Red

let c1 : color = Yellow
let c2 : color = Red
```

- Using data type values:

```
let print_color (c:color) : unit =
  match c with
  | Blue ->
  | Yellow ->
  | Green ->
  | Red ->
```

use pattern matching to determine which color you have; act accordingly

Data types

```
type color = Blue | Yellow | Green | Red
```

```
let c1 : color = Yellow
```

```
let c2 : color = Red
```

- Using data type values:

```
let print_color (c:color) : unit =  
  match c with  
  | Blue -> print_string "blue"  
  | Yellow -> print_string "yellow"  
  | Green -> print_string "green"  
  | Red -> print_string "red"
```

Data types

```
type color = Blue | Yellow | Green | Red
```

- oops!:

```
let print_color (c:color) : unit =  
  match c with  
  | Blue -> print_string "blue"  
  | Yellow -> print_string "yellow"  
  | Red -> print_string "red"
```

Warning 8: this pattern-matching is not exhaustive.
Here is an example of a value that is not matched:
Green

Data Types Can Carry Additional Values

- Data types are more than just enumerations of constants:

```
type point = float * float

type simple_shape =
  Circle of point * float
| Square of point * float
```

- Read as: a **simple_shape** is either:
 - a **Circle**, which contains a **pair** of a **point** and **float**, or
 - a **Square**, which contains a **pair** of a **point** and **float**

Data Types Can Carry Additional Values

- Data types are more than just enumerations of constants:

```
type point = float * float
```

```
type simple_shape =  
  Circle of point * float  
| Square of point * float
```

```
let origin : point = (0.0, 0.0)
```

```
let circ1 : simple_shape = Circle (origin, 1.0)
```

```
let circ2 : simple_shape = Circle ((1.0, 1.0), 5.0)
```

```
let square : simple_shape = Square (origin, 2.3)
```

Data Types Can Carry Additional Values

- Data types are more than just enumerations of constants:

```
type point = float * float
```

```
type simple_shape =  
  Circle of point * float  
| Square of point * float
```

```
let simple_area (s:simple_shape) : float =  
  match s with  
  | Circle (_, radius) -> 3.14 *. radius *. radius  
  | Square (_, side) -> side *. side
```

Compare

- Data types are more than just enumerations of constants:

```
type point = float * float

type simple_shape =
  | Circle of point * float
  | Square of point * float

let simple_area (s:simple_shape) : float =
  match s with
  | Circle (_, radius) -> 3.14 *. radius *. radius
  | Square (_, side) -> side *. side
```

```
type my_shape = point * float

let simple_area (s:my_shape) : float =
  (3.14 *. radius *. radius)      ????  (side *. side)
```

More General Shapes

```
type point = float * float

type shape =
  Square of float
| Ellipse of float * float
| RtTriangle of float * float
| Polygon of point list
```

Square $s =$

RtTriangle (s_1, s_2) =

Ellipse (r_1, r_2) =

RtTriangle [$p_1; \dots; p_5$] =

More General Shapes

```
type point = float * float
type radius = float
type side = float

type shape =
  Square of side
  | Ellipse of radius * radius
  | RtTriangle of side * side
  | Polygon of point list
```

Type abbreviations can aid readability

Square $s =$

RtTriangle (s_1, s_2) =

Ellipse (r_1, r_2) =

RtTriangle [$p_1; \dots; p_5$] =

More General Shapes

```
type point = float * float
type radius = float
type side = float

type shape =
  | Square of side
  | Ellipse of radius * radius
  | RtTriangle of side * side
  | Polygon of point list
```

Square builds a shape
from a single side

RtTriangle builds a shape
from a pair of sides

```
let sq    : shape = Square 17.0
let ell   : shape = Ellipse (1.0, 2.0)
let rt    : shape = RtTriangle (1.0, 1.0)
let poly  : shape = Polygon [(0., 0.); (1., 0.); (0.; 1.)]
```

they are all shapes;
they are constructed in
different ways

Polygon builds a shape
from a list of points
(where each point is itself a pair)

More General Shapes

```
type point = float * float
type radius = float
type side = float

type shape =
  Square of side
| Ellipse of radius * radius
| RtTriangle of side * side
| Polygon of point list
```

```
let area (s : shape) : float =
  match s with
  | Square s ->
  | Ellipse (r1, r2) ->
  | RtTriangle (s1, s2) ->
  | Polygon ps ->
```

a data type also defines
a pattern for matching

More General Shapes

```
type point = float * float
type radius = float
type side = float

type shape =
  Square of side
| Ellipse of radius * radius
| RtTriangle of side * side
| Polygon of point list
```

a data type also defines
a pattern for matching

```
let area (s : shape) : float =
  match s with
  | Square s ->
  | Ellipse (r1, r2) ->
  | RtTriangle (s1, s2) ->
  | Polygon ps ->
```

Square carries a value
with type **float** so **s** is
a pattern for float values

RtTriangle carries a value
with type **float * float**
so **(s1, s2)** is a pattern
for that type

More General Shapes

```
type point = float * float
type radius = float
type side = float

type shape =
  Square of side
| Ellipse of radius * radius
| RtTriangle of side * side
| Polygon of point list
```

```
let area (s : shape) : float =
  match s with
  | Square s -> s *. s
  | Ellipse (r1, r2) -> r1 *. r2
  | RtTriangle (s1, s2) -> s1 *. s2 /. 2.
  | Polygon ps -> ???
```

a data type also defines
a pattern for matching

Computing Area

- How do we compute polygon area?
- For convex polygons:
 - Case: the polygon has fewer than 3 points:
 - it has 0 area! (it is a line or a point or nothing at all)
 - Case: the polygon has 3 or more points:
 - Compute the area of the triangle formed by the first 3 vertices
 - Delete the second vertex to form a new polygon
 - Sum the area of the triangle and the new polygon

Computing Area

- How do we compute polygon area?
- For convex polygons:
 - Case: the polygon has fewer than 3 points:
 - it has 0 area! (it is a line or a point or nothing at all)
 - Case: the polygon has 3 or more points:
 - Compute the area of the triangle formed by the first 3 vertices
 - Delete the second vertex to form a new polygon
 - Sum the area of the triangle and the new polygon
- Note: This is a beautiful **inductive algorithm**:
 - the area of a polygon with n points is computed in terms of a smaller polygon with only $n-1$ points!

Computing Area

```
let area (s : shape) : float =  
  match s with  
  | Square s -> s *. s  
  | Ellipse (r1, r2) -> r1 *. r2  
  | RtTriangle (s1, s2) -> s1 *. s2 /. 2.  
  | Polygon ps -> poly_area ps
```

This pattern says the list has at least 3 items

```
let poly_area (ps : point list) : float =  
  match ps with  
  | p1 :: p2 :: p3 :: tail ->  
    tri_area p1 p2 p3 +. poly_area (p1::p3::ps)  
  | _ -> 0.
```

Computing Area

```
let tri_area (p1:point) (p2:point) (p3:point) : float =
  let a = distance p1 p2 in
  let b = distance p2 p3 in
  let c = distance p3 p1 in
  let s = 0.5 *. (a +. b +. c) in
  sqrt (s *. (s -. a) *. (s -. b) *. (s -. c))
```

```
let rec poly_area (ps : point list) : float =
  match ps with
  | p1 :: p2 :: p3 :: tail ->
    tri_area p1 p2 p3 +. poly_area (p1::p3::ps)
  | _ -> 0.
```

```
let area (s : shape) : float =
  match s with
  | Square s -> s *. s
  | Ellipse (r1, r2)-> r1 *. r2
  | RtTriangle (s1, s2) -> s1 *. s2 /. 2.
  | Polygon ps -> poly_area ps
```

INDUCTIVE DATA TYPES

Inductive data types

- We can use data types to define inductive data
- A binary tree is:
 - a **Leaf** containing no data
 - a **Node** containing a **key**, a **value**, a left **subtree** and a right **subtree**

Inductive data types

- We can use data types to define inductive data
- A binary tree is:
 - a **Leaf** containing no data
 - a **Node** containing a **key**, a **value**, a left subtree and a right subtree

```
type key = string
type value = int

type tree =
  Leaf
| Node of key * value * tree * tree
```

Inductive data types

```
type key = int
type value = string

type tree =
  Leaf
| Node of key * value * tree * tree
```

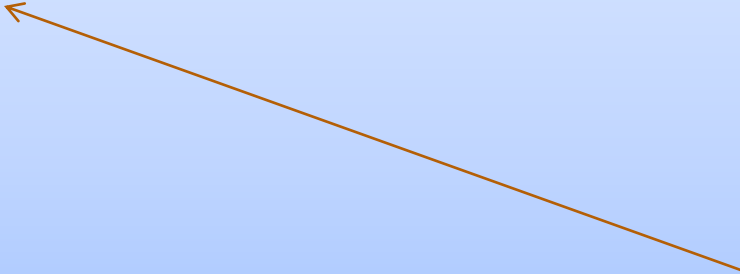

```
let rec insert (t:tree) (k:key) (v:value) : tree =
```

Inductive data types

```
type key = int
type value = string

type tree =
  Leaf
| Node of key * value * tree * tree
```

```
let rec insert (t:tree) (k:key) (v:value) : tree =
  match t with
  | Leaf ->
  | Node (k', v', left, right) ->
```

Again, the type definition specifies the cases you must consider

Inductive data types

```
type key = int
type value = string

type tree =
  Leaf
| Node of key * value * tree * tree
```

```
let rec insert (t:tree) (k:key) (v:value) : tree =
  match t with
  | Leaf -> Node (k, v, Leaf, Leaf)
  | Node (k', v', left, right) ->
```

Inductive data types

```
type key = int
type value = string

type tree =
  Leaf
| Node of key * value * tree * tree
```

```
let rec insert (t:tree) (k:key) (v:value) : tree =
  match t with
  | Leaf -> Node (k, v, Leaf, Leaf)
  | Node (k', v', left, right) ->
    if k < k' then
      Node (k', v', insert left k v, right)
    else if k > k' then
      Node (k', v', left, insert right k v)
    else
      Node (k, v, left, right)
```

Inductive data types

```
type key = int
type value = string

type tree =
  Leaf
| Node of key * value * tree * tree
```

```
let rec insert (t:tree) (k:key) (v:value) : tree =
  match t with
  | Leaf -> Node (k, v, Leaf, Leaf)
  | Node (k', v', left, right) ->
    if k < k' then
      Node (k', v', insert left k v, right)
    else if k > k' then
      Node (k', v', left, insert right k v)
    else
      Node (k, v, left, right)
```

Inductive data types

```
type key = int
type value = string

type tree =
  Leaf
| Node of key * value * tree * tree
```

```
let rec insert (t:tree) (k:key) (v:value) : tree =
  match t with
  | Leaf -> Node (k, v, Leaf, Leaf)
  | Node (k', v', left, right) ->
    if k < k' then
      Node (k', v', insert left k v, right)
    else if k > k' then
      Node (k', v', left, insert right k v)
    else
      Node (k, v, left, right)
```

Inductive data types: Another Example

- Recall, we used the type "int" to represent natural numbers
 - but that was kind of broken: it also contained negative numbers
 - we had to use a dynamic test to guard entry to a function:

```
let double (n : int) : int =  
  if n < 0 then  
    raise (Failure "negative input!")  
  else  
    double_nat n
```

- it would be nice if there was a way to define the natural numbers **exactly**, and use OCaml's type system to guarantee no client ever attempts to double a negative number

Inductive data types

- Recall, a natural number n is either:
 - zero, or
 - $m + 1$
- We use a data type to represent this definition exactly:

Inductive data types

- Recall, a natural number n is either:
 - zero, or
 - $m + 1$
- We use a data type to represent this definition exactly:

```
type nat = Zero | Next of nat
```

Inductive data types

- Recall, a natural number n is either:
 - zero, or
 - $m + 1$
- We use a data type to represent this definition exactly:

```
type nat = Zero | Next of nat

let rec nat_to_int (n : nat) : int =
  match n with
  | Zero -> 0
  | Next n -> 1 + nat_to_int n
```

Inductive data types

- Recall, a natural number n is either:
 - zero, or
 - $m + 1$
- We use a data type to represent this definition exactly:

```
type nat = Zero | Next of nat

let rec nat_to_int (n : nat) : int =
  match n with
  | Zero -> 0
  | Next n -> 1 + nat_to_int n

let rec double_nat (n : nat) : nat =
  match n with
  | Zero -> Zero
  | Next m -> Next (Next (double_nat m))
```

AN EXERCISE IN TYPE DESIGN

Example Type Design

- A **GML document** consists of:
 - a list of **elements**
- An **element** is either:
 - a **word** or **markup** applied to an element
- **Markup** is either:
 - **italicize**, **bold**, or a **font name**

Example Type Design

- A **GML document** consists of:
 - a list of **elements**
- An **element** is either:
 - a **word** or **markup** applied to an element
- **Markup** is either:
 - **italicize**, **bold**, or a **font name**

```
type markup = Ital | Bold | Font of string
```

```
type elt =  
  Words of string list  
| Markup of markup * elt
```

```
type doc = elt list
```

Example Data

```
type markup = Ital | Bold | Font of string
```

```
type elt =  
  Words of string list  
| Markup of markup * elt
```

```
type doc = elt list
```

```
let d = [ Markup (Bold,  
                Markup (Font "Arial",  
                        Words ["Chapter"; "One"]));  
  
          Words ["It"; "was"; "a"; "dark";  
                "&"; "stormy; "night."; "A"];  
  
          Markup (Ital, Words ["shot"]);  
  
          Words ["rang"; "out."] ];;
```

Challenge

- Change all of the “**Arial**” fonts in a document to “**Courier**”.
- Of course, when we program functionally, we implement *change* via a function that
 - receives one data structure as input
 - builds a new (different) data structure as an output

Challenge

- Change all of the “**Arial**” fonts in a document to “**Courier**”.

```
type markup = Ital | Bold | Font of string
```

```
type elt =  
  Words of string list  
| Markup of markup * elt
```

```
type doc = elt list
```

Challenge

- Change all of the “Arial” fonts in a document to “Courier”.

```
type markup = Ital | Bold | Font of string

type elt =
  Words of string list
| Markup of markup * elt

type doc = elt list
```

- Technique: approach the problem top down, work on **doc** first:

```
let rec chfonts (elts:doc) : doc =
```

Challenge

- Change all of the “**Arial**” fonts in a document to “**Courier**”.

```
type markup = Ital | Bold | Font of string

type elt =
  Words of string list
| Markup of markup * elt

type doc = elt list
```

- Technique: approach the problem top down, work on **doc** first:

```
let rec chfonts (elts:doc) : doc =
  match elts with
  | [] ->
  | hd::tl ->
```

Challenge

- Change all of the “**Arial**” fonts in a document to “**Courier**”.

```
type markup = Ital | Bold | Font of string

type elt =
  Words of string list
| Markup of markup * elt

type doc = elt list
```

- Technique: approach the problem top down, work on **doc** first:

```
let rec chfonts (elts:doc) : doc =
  match elts with
  | [] -> []
  | hd::tl -> (chfont hd)::(chfonts tl)
```

Changing fonts in an element

- Change all of the “**Arial**” fonts in a document to “**Courier**”.

```
type markup = Ital | Bold | Font of string

type elt =
  Words of string list
| Markup of markup * elt

type doc = elt list
```

- Next work on changing the font of an **element**:

```
let rec chfont (e:elt) : elt =
```

Changing fonts in an element

- Change all of the “**Arial**” fonts in a document to “**Courier**”.

```
type markup = Ital | Bold | Font of string

type elt =
  Words of string list
| Markup of markup * elt

type doc = elt list
```

- Next work on changing the font of an **element**:

```
let rec chfont (e:elt) : elt =
  match e with
  | Words ws ->
  | Markup (m,e) ->
```

Changing fonts in an element

- Change all of the “**Arial**” fonts in a document to “**Courier**”.

```
type markup = Ital | Bold | Font of string

type elt =
  Words of string list
| Markup of markup * elt

type doc = elt list
```

- Next work on changing the font of an **element**:

```
let rec chfont (e:elt) : elt =
  match e with
  | Words ws -> Words ws
  | Markup (m,e) ->
```

Changing fonts in an element

- Change all of the “**Arial**” fonts in a document to “**Courier**”.

```
type markup = Ital | Bold | Font of string

type elt =
  Words of string list
| Markup of markup * elt

type doc = elt list
```

- Next work on changing the font of an **element**:

```
let rec chfont (e:elt) : elt =
  match e with
  | Words ws -> Words ws
  | Markup(m,e) -> Markup(chmarkup m, chfont e)
```

Changing fonts in an element

- Change all of the “**Arial**” fonts in a document to “**Courier**”.

```
type markup = Ital | Bold | Font of string

type elt =
  Words of string list
| Markup of markup * elt

type doc = elt list
```

- Next work on changing a **markup**:

```
let chmarkup (m:markup) : markup =
```

Changing fonts in an element

- Change all of the “**Arial**” fonts in a document to “**Courier**”.

```
type markup = Ital | Bold | Font of string

type elt =
  Words of string list
| Markup of markup * elt

type doc = elt list
```

- Next work on changing a **markup**:

```
let chmarkup (m:markup) : markup =
  match m with
  | Font "Arial" -> Font "Courier"
  | _ -> m
```

Summary: Changing fonts in an element

- Change all of the “**Arial**” fonts in a document to “**Courier**”
- Lesson: function structure follows type structure

```
let chmarkup (m:markup) : markup =
  match m with
  | Font "Arial" -> Font "Courier"
  | _ -> m

let rec chfont (e:elt) : elt =
  match e with
  | Words ws -> Words ws
  | Markup(m,e) -> Markup(chmarkup m, chfont e)

let rec chfonts (elts:doc) : doc =
  match elts with
  | [] -> []
  | hd::tl -> (chfont hd)::(chfonts tl)
```

Poor Style

- Consider again our definition of markup and markup change:

```
type markup =  
  Ital | Bold | Font of string  
  
let chmarkup (m:markup) : markup =  
  match m with  
  | Font "Arial" -> Font "Courier"  
  | _ -> m
```

Poor Style

- What if we make a change:

```
type markup =  
  Ital | Bold | Font of string | TTFont of string  
  
let chmarkup (m:markup) : markup =  
  match m with  
  | Font "Arial" -> Font "Courier"  
  | _ -> m
```

the underscore silently catches all possible alternatives

this may not be what we want -- perhaps there is an Arial TT font

it is better if we are alerted of all functions whose implementation may need to change

Better Style

- Original code:

```
type markup =  
  Ital | Bold | Font of string  
  
let chmarkup (m:markup) : markup =  
  match m with  
  | Font "Arial" -> Font "Courier"  
  | Ital | Bold -> m
```

Better Style

- Updated code:

```
type markup =  
  Ital | Bold | Font of string | TTFont of string  
  
let chmarkup (m:markup) : markup =  
  match m with  
  | Font "Arial" -> Font "Courier"  
  | Ital | Bold -> m
```

```
..match m with  
  | Font "Arial" -> Font "Courier"  
  | Ital | Bold -> m..
```

Warning 8: this pattern-matching is not exhaustive.

Here is an example of a value that is not matched:

```
TTFont _
```

Better Style

- Updated code, fixed:

```
type markup =  
  Ital | Bold | Font of string | TTFont of string  
  
let chmarkup (m:markup) : markup =  
  match m with  
  | Font "Arial" -> Font "Courier"  
  | TTFont "Arial" -> TTFont "Courier"  
  | TTFont s -> TTFont s  
  | Ital | Bold -> m
```

- **Lesson:** use the type checker where possible to help you maintain your code

To Summarize

- Design recipe for writing Ocaml code:
 - write down English specifications
 - try to break problem into obvious sub-problems
 - write down some sample test cases
 - write down the signature (types) for the code
 - use the signature to guide construction of the code:
 - tear apart inputs using pattern matching
 - make sure to cover all of the cases! (Ocaml will tell you)
 - handle each case, building results using data constructor
 - this is where human intelligence comes into play
 - the “skeleton” given by types can almost be done automatically!
 - clean up your code
 - use your sample tests (and ideally others) to ensure correctness

A couple of practice problems

- Write a function that gets rid of immediately redundant markup in a document. That is, `Markup(Ital, Markup(Ital,e))` can be simplified to `Markup(Ital,e)`
 - write maps and folds over markups
- Design a datatype to describe bibliography entries for publications. Some publications are journal articles, others are books, and others are conference papers. Journals have a name, number and issue; books have an ISBN number; All of these entries should have a title and author.
 - design a sorting function
 - design maps and folds over your bibliography entries

END
