4. GREEDY ALGORITHMS I

- coin changing
- interval scheduling
- scheduling to minimize lateness
- optimal caching

Coin changing

Goal. Given currency denominations: 1, 5, 10, 25, 100, devise a method to pay amount to customer using fewest number of coins.

Ex. 34¢.

Cashier’s algorithm. At each iteration, add coin of the largest value that does not take us past the amount to be paid.

Ex. $2.89.

Cashier’s algorithm

At each iteration, add coin of the largest value that does not take us past the amount to be paid.

CashiersAlgorithm(x, c_1, c_2, ..., c_n)

\[
\begin{align*}
S &\leftarrow \emptyset \quad \text{set of coins selected} \\
\text{WHILE } x > 0 & \\
& \quad k \leftarrow \text{largest coin denomination } c_k \text{ such that } c_k \leq x \\
& \quad \text{IF no such } k, \text{ RETURN "no solution"} \\
& \quad \text{ELSE} \\
& \quad \quad x \leftarrow x - c_k \\
& \quad \quad S \leftarrow S \cup \{ k \} \\
& \quad \text{RETURN } S
\end{align*}
\]

Q. Is cashier’s algorithm optimal?
Properties of optimal solution

Property. Number of pennies ≤ 4.
Pf. Replace 5 pennies with 1 nickel.

Property. Number of nickels ≤ 1.

Property. Number of quarters ≤ 3.

Property. Number of nickels + number of dimes ≤ 2.
Pf.
- Replace 3 dimes and 0 nickels with 1 quarter and 1 nickel;
- Replace 2 dimes and 1 nickel with 1 quarter.
- Recall: at most 1 nickel.

Analysis of cashier’s algorithm

Theorem. Cashier’s algorithm is optimal for U.S. coins: 1, 5, 10, 25, 100.
Pf. [by induction on \( x \)]
- Consider optimal way to change \( c_k \leq x < c_{k+1} \): greedy takes coin \( k \).
- We claim that any optimal solution must also take coin \( k \).
  - if not, it needs enough coins of type \( c_1, \ldots, c_{k-1} \) to add up to \( x \)
  - table below indicates no optimal solution can do this
- Problem reduces to coin-changing \( x - c_k \) cents, which, by induction, is optimally solved by cashier’s algorithm.

<table>
<thead>
<tr>
<th>( k )</th>
<th>( c_k )</th>
<th>all optimal solutions must satisfy</th>
<th>max value of coins ( c_1, c_2, \ldots, c_k ) in any OPT</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>( P \leq 4 )</td>
<td>-</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
<td>( N \leq 1 )</td>
<td>4</td>
</tr>
<tr>
<td>3</td>
<td>10</td>
<td>( N + D \leq 2 )</td>
<td>4 + 5 = 9</td>
</tr>
<tr>
<td>4</td>
<td>25</td>
<td>( Q \leq 3 )</td>
<td>20 + 4 = 24</td>
</tr>
<tr>
<td>5</td>
<td>100</td>
<td>no limit</td>
<td>75 + 24 = 99</td>
</tr>
</tbody>
</table>

Cashier’s algorithm for other denominations

Q. Is cashier’s algorithm for any set of denominations?

A. No. Consider U.S. postage: 1, 10, 21, 34, 70, 100, 350, 1225, 1500.
  - Cashier’s algorithm: \( 140\text{¢} = 100 + 34 + 1 + 1 + 1 + 1 + 1 + 1 \).
  - Optimal: \( 140\text{¢} = 70 + 70 \).

A. No. It may not even lead to a feasible solution if \( c_1 > 1 \): 7, 8, 9.
  - Cashier’s algorithm: \( 15\text{¢} = 9 + ??\).
  - Optimal: \( 15\text{¢} = 7 + 8 \).

4. Greedy Algorithms I

- coin changing
- interval scheduling
- scheduling to minimize lateness
- optimal caching

Section 4.1
Interval scheduling

- Job $j$ starts at $s_j$ and finishes at $f_j$.
- Two jobs compatible if they don’t overlap.
- Goal: find maximum subset of mutually compatible jobs.

Greedy template. Consider jobs in some natural order. Take each job provided it’s compatible with the ones already taken.

- [Earliest start time] Consider jobs in ascending order of $s_j$.
- [Earliest finish time] Consider jobs in ascending order of $f_j$.
- [Shortest interval] Consider jobs in ascending order of $f_j - s_j$.
- [Fewest conflicts] For each job $j$, count the number of conflicting jobs $c_j$. Schedule in ascending order of $c_j$.

Interval scheduling: earliest-finish-time-first algorithm

**Proposition.** Can implement earliest-finish-time first in $O(n \log n)$ time.
- Keep track of job $j^*$ that was added last to $A$.
- Job $j$ is compatible with $A$ iff $s_j \geq f_{j^*}$.
- Sorting by finish time takes $O(n \log n)$ time.
**Theorem.** The earliest-finish-time-first algorithm is optimal.

**Pf.** [by contradiction]
- Assume greedy is not optimal, and let’s see what happens.
- Let \( i_1, i_2, \ldots, i_r \) denote set of jobs selected by greedy.
- Let \( j_1, j_2, \ldots, j_m \) denote set of jobs in an optimal solution with \( i_1 = j_1, i_2 = j_2, \ldots, i_r = j_r \) for the largest possible value of \( r \).

For the largest possible value of \( r \), why not replace job \( j_{r+1} \) with job \( i_{r+1} \)?

**Interval partitioning.**
- Lecture \( j \) starts at \( s_j \) and finishes at \( f_j \).
- Goal: find minimum number of classrooms to schedule all lectures so that no two lectures occur at the same time in the same room.

**Ex.** This schedule uses 4 classrooms to schedule 10 lectures.

Interval partitioning
- Lecture \( j \) starts at \( s_j \) and finishes at \( f_j \).
- Goal: find minimum number of classrooms to schedule all lectures so that no two lectures occur at the same time in the same room.

**Ex.** This schedule uses 3 classrooms to schedule 10 lectures.
**Interval partitioning: greedy algorithms**

**Greedy template.** Consider lectures in some natural order. Assign each lecture to an available classroom (which one?); allocate a new classroom if none are available.

- [Earliest start time] Consider lectures in ascending order of \( s_j \).
- [Earliest finish time] Consider lectures in ascending order of \( f_j \).
- [Shortest interval] Consider lectures in ascending order of \( f_j - s_j \).
- [Fewest conflicts] For each lecture \( j \), count the number of conflicting lectures \( c_j \). Schedule in ascending order of \( c_j \).

---

**Interval partitioning: earliest-start-time-first algorithm**

**EarlyListItemFirst**(\( n, s_1, s_2, \ldots, s_n, f_1, f_2, \ldots, f_n \))

**Sort** lectures by start time so that \( s_1 \leq s_2 \leq \ldots \leq s_n \).

**Init** \( d \leftarrow 0 \) \hspace{1cm} \text{number of allocated classrooms}

**For** \( j = 1 \) to \( n \)
- **If** lecture \( j \) is compatible with some classroom
  - Schedule lecture \( j \) in any such classroom \( k \).
- **Else**
  - Allocate a new classroom \( d + 1 \).
  - Schedule lecture \( j \) in classroom \( d + 1 \).
  - \( d \leftarrow d + 1 \)

**Return** schedule.

---

**Interval partitioning: earliest-start-time-first algorithm**

**Proposition.** The earliest-start-time-first algorithm can be implemented in \( O(n \log n) \) time.

**Pf.** Store classrooms in a priority queue (key = finish time of its last lecture).
- To determine whether lecture \( j \) is compatible with some classroom, compare \( s_j \) to key of min classroom \( k \) in priority queue.
- To add lecture \( j \) to classroom \( k \), increase key of classroom \( k \) to \( f_j \).
- Total number of priority queue operations is \( O(n) \).
- Sorting by start time takes \( O(n \log n) \) time.

**Remark.** This implementation chooses the classroom \( k \) whose finish time of its last lecture is the earliest.
Interval partitioning: lower bound on optimal solution

**Def.** The depth of a set of open intervals is the maximum number that contain any given time.

**Key observation.** Number of classrooms needed ≥ depth.

**Q.** Does number of classrooms needed always equal depth?

**A.** Yes! Moreover, earliest-start-time-first algorithm finds one.

---

**Interval partitioning: analysis of earliest-start-time-first algorithm**

**Observation.** The earliest-start-time first algorithm never schedules two incompatible lectures in the same classroom.

**Theorem.** Earliest-start-time-first algorithm is optimal.

**Pf.**
- Let \( d \) = number of classrooms that the algorithm allocates.
- Classroom \( d \) is opened because we needed to schedule a lecture, say \( j \), that is incompatible with all \( d - 1 \) other classrooms.
- These \( d \) lectures each end after \( s_j \).
- Since we sorted by start time, all these incompatibilities are caused by lectures that start no later than \( s_j \).
- Thus, we have \( d \) lectures overlapping at time \( s_j + \epsilon \).
- Key observation \( \Rightarrow \) all schedules use \( \geq d \) classrooms. 

---

Scheduling to minimizing lateness

**Minimizing lateness problem.**
- Single resource processes one job at a time.
- Job \( j \) requires \( t_j \) units of processing time and is due at time \( d_j \).
- If \( j \) starts at time \( s_j \), it finishes at time \( f_j = s_j + t_j \).
- Lateness: \( \ell_j = \max \{ 0, f_j - d_j \} \).
- Goal: schedule all jobs to minimize maximum lateness \( L = \max_j \ell_j \).

---

**4. Greedy Algorithms I**

- coin changing
- interval scheduling
- scheduling to minimize lateness
- optimal caching
Minimizing lateness: greedy algorithms

Greedy template. Schedule jobs according to some natural order.

- [Shortest processing time first] Schedule jobs in ascending order of processing time $t_j$.

- [Earliest deadline first] Schedule jobs in ascending order of deadline $d_j$.

- [Smallest slack] Schedule jobs in ascending order of slack $d_j - t_j$.

Minimizing lateness: earliest deadline first

**EarliestDeadlineFirst**($n$, $t_1$, $t_2$, ..., $t_n$, $d_1$, $d_2$, ..., $d_n$)

Sort $n$ jobs so that $d_1 \leq d_2 \leq ... \leq d_n$.

$t ← 0$

For $j = 1$ to $n$

Assign job $j$ to interval $[t, t + t_j]$.

$s_j ← t ; \ f_j ← t + t_j$

$t ← t + t_j$

Return intervals $[s_1, f_1], [s_2, f_2], ..., [s_n, f_n]$.

Max lateness = 1

Minimizing lateness: no idle time

Observation 1. There exists an optimal schedule with no idle time.

Observation 2. The earliest-deadline-first schedule has no idle time.
Minimizing lateness: inversions

**Def.** Given a schedule $S$, an **inversion** is a pair of jobs $i$ and $j$ such that:

$i < j$ but $j$ scheduled before $i$.

---

**Observation 3.** The earliest-deadline-first schedule has no inversions.

**Observation 4.** If a schedule (with no idle time) has an inversion, it has one with a pair of inverted jobs scheduled consecutively.

---

Minimizing lateness: analysis of earliest-deadline-first algorithm

**Theorem.** The earliest-deadline-first schedule $S$ is optimal.

**Pf.** [by contradiction]

Define $S^*$ to be an optimal schedule that has the fewest number of inversions, and let’s see what happens.

- Can assume $S^*$ has no idle time.
- If $S^*$ has no inversions, then $S = S^*$.
- If $S^*$ has an inversion, let $i$-$j$ be an adjacent inversion.
- Swapping $i$ and $j$
  - does not increase the max lateness
  - strictly decreases the number of inversions
- This contradicts definition of $S^*$.

---

Greedy analysis strategies

**Greedy algorithm stays ahead.** Show that after each step of the greedy algorithm, its solution is at least as good as any other algorithm’s.

**Structural.** Discover a simple "structural" bound asserting that every possible solution must have a certain value. Then show that your algorithm always achieves this bound.

**Exchange argument.** Gradually transform any solution to the one found by the greedy algorithm without hurting its quality.

**Other greedy algorithms.** Gale-Shapley, Kruskal, Prim, Dijkstra, Huffman, …
4. **Greedy Algorithms I**

- coin changing
- interval scheduling
- scheduling to minimize lateness
- optimal caching

**Optimal offline caching**

**Caching.**
- Cache with capacity to store $k$ items.
- Sequence of $m$ item requests $d_1, d_2, \ldots, d_m$.
  - Cache hit: item already in cache when requested.
  - Cache miss: item not already in cache when requested: must bring requested item into cache, and evict some existing item, if full.

**Goal.** Eviction schedule that minimizes number of evictions.

**Ex.** $k = 2$, initial cache = ab, requests: a, b, c, b, c, a, a.

**Optimal eviction schedule.** 2 evictions.

**Optimal offline caching: greedy algorithms**

**LIFO / FIFO.** Evict element brought in most (east) recently.

**LRU.** Evict element whose most recent access was earliest.

**LFU.** Evict element that was least frequently requested.

**Optimal offline caching: farthest-in-future (clairvoyant algorithm)**

**Farthest-in-future.** Evict item in the cache that is not requested until farthest in the future.

**Theorem.** [Bélády 1966] FF is optimal eviction schedule.

**Pf.** Algorithm and theorem are intuitive; proof is subtle.
**Reduced eviction schedules**

**Def.** A reduced schedule is a schedule that only inserts an item into the cache in a step in which that item is requested.

![Diagram of reduced eviction schedules](image)

**Claim.** Given any unreduced schedule $S$, can transform it into a reduced schedule $S'$ with no more evictions.

**Pf.** [by induction on number of unreduced items]
- Suppose $S$ brings $d$ into the cache at time $t$, without a request.
- Let $c$ be the item $S$ evicts when it brings $d$ into the cache.
- Case 1: $d$ evicted at time $t'$, before next request for $d$.
- Case 2: $d$ requested at time $t'$ before $d$ is evicted.

![Diagram of reduced eviction schedules](image)

**Farthest-in-future: analysis**

**Theorem.** FF is optimal eviction algorithm.

**Pf.** Follows directly from invariant.

**Invariant.** There exists an optimal reduced schedule $S$ that makes the same eviction schedule as $S_{FF}$ through the first $j$ requests.

**Pf.** [by induction on $j$]
Let $S$ be reduced schedule that satisfies invariant through $j$ requests.

We produce $S'$ that satisfies invariant after $j + 1$ requests.
- Consider $(j + 1)^{th}$ request $d = d_{j+1}$.
- Since $S$ and $S_{FF}$ have agreed up until now, they have the same cache contents before request $j + 1$.
- Case 1: ($d$ is already in the cache). $S' = S$ satisfies invariant.
- Case 2: ($d$ is not in the cache and $S$ and $S_{FF}$ evict the same element). $S' = S$ satisfies invariant.
Farthest-in-future: analysis

Pf. [continued]
• Case 3: \(d\) is not in the cache; \(S_{FF}\) evicts \(e\); \(S\) evicts \(f \neq e\).
  - begin construction of \(S'\) from \(S\) by evicting \(e\) instead of \(f\)
    
    \[
    \begin{array}{c|c|c}
    & \text{same} & f \\
    \hline
    e & j & \text{same} \\
    \hline
    S & \text{e} & f \\
    \hline
    \end{array}
    \]
    \[
    \begin{array}{c|c|c}
    & \text{same} & \text{e} \\
    \hline
    g & j+1 & \text{same} \\
    \hline
    S' & \text{e} & f \\
    \hline
    \end{array}
    \]

  - now \(S'\) agrees with \(S_{FF}\) on first \(j+1\) requests; we show that having element \(f\) in cache is no worse than having element \(e\)

  - let \(S'\) behave the same as \(S\) until \(S'\) is forced to take a different action (because either \(S\) evicts \(e\); or because either \(e\) or \(f\) is requested)

Farthest-in-future: analysis

Let \(j'\) be the first time after \(j+1\) that \(S'\) must take a different action from \(S\), and let \(g\) be item requested at time \(j'\).

- Case 3a: \(g = e\).
  Can't happen with FF since there must be a request for \(f\) before \(e\).

- Case 3b: \(g = f\).
  Element \(f\) can't be in cache of \(S\), so let \(e'\) be the element that \(S\) evicts.
  - if \(e' = e\), \(S'\) accesses \(f\) from cache; now \(S\) and \(S'\) have same cache
  - if \(e' \neq e\), we make \(S'\) evict \(e'\) and brings \(e\) into the cache;
    now \(S\) and \(S'\) have the same cache
  We let \(S'\) behave exactly like \(S\) for remaining requests.

Caching perspective

Online vs. offline algorithms.
- Offline: full sequence of requests is known a priori.
- Online (reality): requests are not known in advance.
- Caching is among most fundamental online problems in CS.

LIFO. Evict page brought in most recently.
LRU. Evict page whose most recent access was earliest.

Theorem. FF is optimal offline eviction algorithm.
- Provides basis for understanding and analyzing online algorithms.
- LRU is \(k\)-competitive. [Section 13.8]
- LIFO is arbitrarily bad.
