

Signals

CS 217

Goals of Today's Lecture

- Overview of signals
 - Notifications sent to a process
 - UNIX signal names and numbers
 - Ways to generate signals
- Signal handling
 - Installing signal handlers
 - Ignoring vs. blocking signals
 - Avoiding race conditions

• Keeping track of the passage of time

- Interval timers
- Real time vs. CPU time

Signals

- Event notification sent to a process at <u>any</u> time
 - An event generates a signal
 - OS stops the process immediately
 - Signal handler executes, and then the process resumes
- Example: user types control-C
 - Event generates the "interrupt" signal (SIGINT)
 - OS stops the process immediately
 - Default handler terminates the process
- Example: process makes illegal memory reference
 - Event generates "segmentation fault" signal (SIGSEGV)
 - OS stops the process immediately
 - Default handler terminates the process, and dumps core,

Sending Signals from Keyboard

• Steps

- Pressing keys generates interrupts to the OS
- OS interprets the key sequence and sends a signal to the running process

• Examples

- Ctrl-C: OS sends an INT signal to the running process
 - By default, the process terminates immediately
- Ctrl-Z: OS sends a TSTP signal to the running process
 - By default, the process suspends execution
- Ctrl-\: OS sends an ABRT signal to the running process.
 By default, the process terminates immediately
- Question: why do we have both Ctrl-C and Ctrl-\?
 Ctrl-\ generates a core file, whereas Ctrl-C does not

Sending Signals From The Shell

- •kill -<signal> <PID>
 - Example: kill -INT 1234
 - Send the INT signal to process with PID 1234
 - Same as pressing Ctrl-C if process 1234 is running
 - If no signal name or number is specified, the default is to send an SIGTERM signal to the process,

•fg

- The command is "foreground"
- \circ On UNIX shells, this command will send a CONT signal
- Resume execution of the process (that was suspended with Ctrl-Z or a command "bg")
- See man pages for fg and bg

Sending Signals from a Program

- The kill command is implemented by a system call #include <sys/types.h> #include <signal.h> int kill(pid_t pid, int sig);
- Example: send a signal to itself
 if (kill(getpid(), SIGABRT))
 exit(0);
 - o The equivalent in ANSI C is: int raise(int sig);

```
if (raise(SIGABRT) > 0)
    exit(1);
```

Predefined and Defined Signals

- Find out the predefined signals
 % kill -1
 - % HUP INT QUIT ILL TRAP ABRT BUS FPE KILL USR1 SEGV USR2 PIPE ALRM TERM STKFLT CHLD CONT STOP TSTP TTIN TTOU URG XCPU XFSZ VTALRM PROF WINCH POLL PWR SYS RTMIN RTMIN+1 RTMIN+2 RTMIN+3 RTMAX-3 RTMAX-2 RTMAX-1 RTMAX
- Applications can define their own signals
 An application can define signals with unused values

Some Predefined Signals in UNIX

Ŧ	#define	SIGHUP	1	/*	Hangup (POSIX). */
1	#define	SIGINT	2	/*	Interrupt (ANSI). */
Ŧ	#define	SIGQUIT	3	/*	Quit (POSIX). */
1	#define	SIGILL	4	/*	Illegal instruction (ANSI). */
Ŧ	#define	SIGTRAP	5	/*	Trace trap (POSIX). */
1	#define	SIGABRT	6	/*	Abort (ANSI). */
Ŧ	#define	SIGFPE	8	/*	Floating-point exception (ANSI). */
1	#define	SIGKILL	9	/*	Kill, unblockable (POSIX). */
Ŧ	#define	SIGUSR1	10	/ *	User-defined signal 1 (POSIX). */
1	#define	SIGSEGV	11	/*	Segmentation violation (ANSI). */
Ŧ	#define	SIGUSR2	12	/ *	User-defined signal 2 (POSIX). */
Ŧ	#define	SIGPIPE	13	/ *	Broken pipe (POSIX). */
1	#define	SIGALRM	14	/*	Alarm clock (POSIX). */
1	#define	SIGTERM	15	/*	Termination (ANSI). */
Ŧ	#define	SIGCHLD	17	/ *	Child status has changed (POSIX). */
1	#define	SIGCONT	18	/*	Continue (POSIX). */
1	#define	SIGSTOP	19	/*	<pre>Stop, unblockable (POSIX). */</pre>
1	#define	SIGTSTP	20	/*	Keyboard stop (POSIX). */
Ŧ	#define	SIGTTIN	21	/ *	Background read from tty (POSIX). */
ł	#define	SIGTTOU	22	/ *	Background write to tty (POSIX). */
1	#define	SIGPROF	27	/*	Profiling alarm clock (4.2 BSD). */

Signal Handling

- Signals have default handlers
 - Usually, terminate the process and generate core image
- Programs can over-ride default for most signals
 - Define their own handlers
 - Ignore certain signals, or temporarily block them
- Two signals are not "catchable" in user programs
 - KILL
 - Terminate the process immediately
 - Catchable termination signal is TERM
 - STOP
 - Suspend the process immediately
 - Can resume the process with signal CONT
 - Catchable suspension signal is TSTP

Installing A Signal Handler

- Predefined signal handlers • SIG_DFL: Default handler
 - **SIG_IGN:** Ignore the signal
- To install a handler, use #include <signal.h>

```
typedef void (*sighandler_t)(int);
sighandler_t signal(int sig, sighandler_t handler);
```

- Handler will be invoked, when signal sig occurs
- Return the old handler on success; SIG_ERR on error
- On most UNIX systems, after the handler executes, the OS resets the handler to SIG_DFL

Example: Clean Up Temporary File

Program generates a lot of intermediate results
 Store the data in a temporary file (e.g., "temp.xxx")
 Remove the file when the program ends (i.e., unlink)

```
#include <stdio.h>
char *tmpfile = "temp.xxx";
int main() {
   FILE *fp;
   fp = fopen(tmpfile, "rw");
   fclose(fp);
   unlink(tmpfile);
   return(0);
```

Problem: What about Control-C?

- What if user hits control-C to interrupt the process?
 Generates a SIGINT signal to the process
 Default handling of SIGINT is to terminate the process
- Problem: the temporary file is not removed

 Process dies before unlink(tmpfile) is performed
 Can lead to lots of temporary files lying around
- Challenge in solving the problem

 Control-C could happen at any time
 Which line of code will be interrupted???
- Solution: signal handler
 - Define a "clean-up" function to remove the temporary file
 - Install the function as a signal handler

Solution: Clean-Up Signal Handler

```
#include <stdio.h>
```

```
#include <signal.h>
```

```
char *tmpfile = "temp.xxx";
```

```
void cleanup() {
    unlink(tmpfile);
```

```
exit(1);
```

```
int main() {
```

```
if (signal(SIGINT, cleanup) == SIG_ERR)
```

```
fprintf(stderr, "Cannot set up signal\n");
```

```
return(0);
```

Ignoring a Signal

- Completely disregards the signal
 Signal is delivered and "ignore" handler takes no action
 E.g., signal(SIGINT, SIG_IGN) to ignore the ctrl-C
- - Causes <u>all</u> processes to receive the control-
 - Solution: shell arranges to ignore interrupts
 - All background processes use the SIG_IGN handler

Example: Clean-Up Signal Handler

```
#include <stdio.h>
```

```
#include <signal.h>
```

```
char *tmpfile = "temp.xxx";
```

```
void cleanup() {
    unlink(tmpfile);
```

```
exit(1);
```

int main() {

```
Problem: What if this is a background process that was ignoring SIGINT???
```

```
if (signal(SIGINT, cleanup) == SIG ERR)
```

```
fprintf(stderr, "Cannot set up signal\n");
```

```
•••
```

```
return(0);
```

Solution: Check for Ignore Handler

- signal() system call returns previous handler
 - E.g., signal(SIGINT, SIG_IGN)
 - Returns **sig_ign** if signal was being ignored
 - Sets the handler (back) to **SIG_IGN**
- Solution: check the value of previous handler
 - If previous handler was "ignore"
 - Continue to ignore the interrupt signal
 - Else
 - Change the handler to "cleanup"

Solution: Modified Signal Call

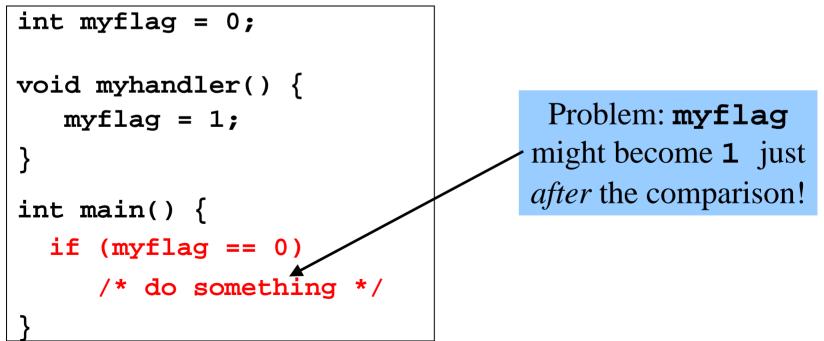

```
#include <stdio.h>
#include <signal.h>
char *tmpfile = "temp.xxx";
void cleanup() {
   unlink(tmpfile);
   exit(1);
                     Solution: If SIGINT was ignored,
                        simply keep on ignoring it!
int main() {
   if (signal(SIGINT, SIG IGN) != SIG IGN)
      signal(SIGINT, cleanup);
   return(0);
```

Blocking or Holding a Signal

- Temporarily defers handling the signal

 Process can prevent selected signals from occurring
 ... while ensuring the signal is not forgotten
 ... so the process can handle the signal later
- Example: testing a global variable set by a handler

Race Condition: Salary Example

```
void add_salary_to_savings() {
```

```
int tmp;
```

```
tmp = savingsBalance;
```

```
tmp += monthlySalary;
```

```
savingsBalance = tmp;
```

Handler for "Monthly salary signal"

Race Condition: Handler Starts

```
void add_salary_to_savings() {
    int tmp;
```

```
tmp = savingsBalance; 2000
```

```
tmp += monthlySalary;
```

```
savingsBalance = tmp;
```

Race Condition: Signal Again

```
void add salary to savings() {
    int tmp;
    tmp = savingsBalance; 2000
    tmp += monthlySalary;
    savingsBalance = tmp;
            void add_salary_to_savings() {
                int tmp;
                tmp = savingsBalance;
                tmp += monthlySalary;
                savingsBalance = tmp;
```

Race Condition: 2nd Handler Call

```
void add salary to savings() {
    int tmp;
   tmp = savingsBalance; 2000
    tmp += monthlySalary;
    savingsBalance = tmp;
            void add_salary_to_savings() {
                int tmp;
                tmp = savingsBalance; 2000
                tmp += monthlySalary;
                savingsBalance = tmp;
```

Race Condition: Back to 1st Handler

```
void add salary to savings() {
    int tmp;
    tmp = savingsBalance; 2000
    tmp += monthlySalary;
    savingsBalance = tmp;
            void add_salary_to_savings() {
                int tmp;
                tmp = savingsBalance;
                tmp += monthlySalary;
               ; savingsBalance = tmp; 2050
```

Race Condition: Lost Money!

```
void add salary to savings() {
    int tmp;
                           2000
    tmp = savingsBalance;
    tmp += monthlySalary;
    savingsBalance = tmp; 2050
            void add_salary_to_savings() {
                int tmp;
                tmp = savingsBalance;
                tmp += monthlySalary;
               savingsBalance = tmp;
```

You just lost a month's worth of salary!

Blocking Signals

- Why block signals?
 - An application wants to ignore certain signals
 - Avoid race conditions when another signal happens in the middle of the signal handler's execution
- Two ways to block signals
 Affect all signal handlers sigprocmask()
 - Affect a specific handler sigaction()

Block Signals

- Each process has a signal mask in the kernel
 OS uses the mask to decide which signals to deliver
 User program can modify mask with sigprocmask()
- int sigprocmask() with three parameters
 - How to modify the signal mask (int how)
 - SIG_BLOCK: Add set to the current mask
 - **SIG_UNBLOCK:** Remove **set** from the current mask
 - SIG_SETMASK: Install set as the signal mask
 - Set of signals to modify (const sigset_t *set)
 - Old signals that were blocked (sigset_t *oset)
- Functions for constructing sets
 sigemptyset(), sigaddset(), ...

Block Signals

- Each process has a signal mask in the kernel
 OS uses the mask to decide which signals to deliver
 User program can modify mask with sigprocmask()
- int sigprocmask() with three parameters
 - How to modify the signal mask (int how)
 - SIG_BLOCK: Add set to the current mask
 - **SIG_UNBLOCK:** Remove **set** from the current mask
 - SIG_SETMASK: Install set as the signal mask
 - Set of signals to modify (const sigset_t *set)
 - Old signals that were blocked (sigset_t *oset)
- Functions for constructing sets
 sigemptyset(), sigaddset(), ...

Example: Block Interrupt Signal

#include <stdio.h>

#include <signal.h>

```
sigset_t newsigset;
```

```
int main() {
```

...

```
sigemptyset(&newsigset);
```

```
sigaddset(&newsigset, SIGINT);
```

if (sigprocmask(SIG_BLOCK, &newsigset, NULL) < 0)
 fprintf(stderr, "Could not block signal\n");</pre>

Problem: Blocking Signals in Handler

- Goal: block certain signals within a handler
 Another signal might arrive at the start of the handler
 ... before calling the system call to block signals
- Solution: install handler and the mask together
 - Sigaction() system call, with three parameters
 - Signal number (int signum)
 - Set new signal action (const struct sigaction *)
 - Examine old signal action (struct sigaction *)
 - Sigaction data structure
 - Handler for the signal
 - Mask of additional signals to block during the handler
 - Flags controlling delivery of the signal

Sigaction() vs. Signal()

- Benefits of signal()
 - Set the mask and handler together
 - Examine the existing handler without reassigning it
 - Provide handler with information about process state
- You should not mix the two system calls
 - They interact in strange ways
 - In Assignment #7, we recommend using sigaction()

Er Consumer

Keeping Track of Passage of Time

- Interval timers
 - Generate a signal after a specific time interval
- Real time (or wall-clock time)
 - Elapsed time, independent of activity
 - Not an accurate measure of execution time
 - Timer generates a SIGALRM signal
- Virtual time (or CPU time)
 - Time the process spends running
 - Doesn't include spent by other processes
 - Timer generates a SIGPROF signal

Interval Timer in Real Time

- Sends an SIGALRM signal after n seconds unsigned int alarm(unsigned seconds);
- Example

```
#include <signal.h> /* signal names and API */
void catch_alarm(int sig) {
   if (signal(SIGALRM, catch alarm) == SIG ERR)
      ...;
main(void) {
   if (signal(SIGALRM, catch alarm) == SIG ERR)
      . . . ;
   alarm(10);
   • • • ;
```

Interval Timer in CPU Time

```
    Send an signal after an interval timer expires
    #include <sys/time.h>
    int setitimer(int which,
        const struct itimerval *value,
        struct itimerval *value);
```

```
• Example: SIGPROF signal every 10 milliseconds struct itimerval timer;
```

```
timer.it_value.tv_sec = 0;
timer.it_value.tv_usec = 10000;  /* 10ms */
timer.it_interval.tv_sec = 0;
timer.it_interval.tv_usec = 10000; /* reload 10ms */
if (setitimer(ITIMER_PROF, &timer, NULL) == ...)
...;
```

• On Linux, the minimal effective granularity is **10ms**.

Conclusions

Signals

- An asynchronous event mechanism
- Use **sigaction()** and blocking to avoid race conditions
- Signal handlers should be simple and short
- Most predefined signals are :catchable"

Interval timers

- Real time (SIGALRM) or CPU time (SIGPROF)
- Linux imposes 10ms as the minimal granularity
