

Laplacian Mesh Editing

COS 526 – Fall 2010

Guest lecturer: Yaron Lipman

(most of the) Slides borrowed from: Olga Sorkine

Outline

- Differential surface representation
- Ideas and applications
 - Compact shape representation
 - Mesh editing and manipulation
 - Membrane and flattening
 - Generalizing Fourier basis for surfaces

Motivation

- Meshes are great, but:
 - Geometry is represented in a *global* coordinate system
 - Single Cartesian coordinate of a vertex doesn't say much

Differential coordinates

- Represent a point **relative** to it's neighbors.
- Represent **local detail** at each surface point
 - better describe the shape
- Linear transition from global to differential
- Useful for operations on surfaces where surface details are important

Differential coordinates

"Local control for mesh morphing", Alexa 01

- Detail = surface – *smooth*(surface)
- Smoothing = averaging

$$\delta_i = \mathbf{v}_i - \frac{1}{d_i} \sum_{j \in N(i)} \mathbf{v}_j$$

$$\delta_i = \sum_{j \in N(i)} \frac{1}{d_i} (\mathbf{v}_i - \mathbf{v}_j)$$

Connection to the smooth case

- The direction of δ_i approximates the normal
- The size approximates the mean curvature

$$\delta_i = \frac{1}{d_i} \sum_{j \in N(i)} (\mathbf{v}_i - \mathbf{v}_j)$$

$$\frac{1}{len(\gamma)} \int_{\mathbf{v} \in \gamma} (\mathbf{v}_i - \mathbf{v}) ds$$

$$\lim_{len(\gamma) \rightarrow 0} \frac{1}{len(\gamma)} \int_{\mathbf{v} \in \gamma} (\mathbf{v}_i - \mathbf{v}) ds = H(\mathbf{v}_i) \mathbf{n}_i$$

Weighting schemes

$$\delta_i = \frac{\sum_{j \in N(i)} w_{ij} (\mathbf{v}_i - \mathbf{v}_j)}{\sum_{j \in N(i)} w_{ij}}$$

- Ignore geometry

$$\delta_{\text{umbrella}}: w_{ij} = 1$$

- Integrate over circle around vertex

$$\delta_{\text{mean value}}: w_{ij} = \tan \phi_{ij}/2 + \tan \phi_{i,j+1}/2$$

- Integrate over Voronoi region of vertex

$$\delta_{\text{cotangent}}: w_{ij} = \cot \alpha_{ij} + \cot \beta_{ij}$$

September 12, 2005

7/90

Laplacian matrix

[Taubin 95]

- The transition between the δ and xyz is linear:

$$\delta_i = \sum_{j \in N(i)} w_{ij} (\mathbf{v}_i - \mathbf{v}_j)$$

$$\begin{matrix} L & \mathbf{v}_x & = & \delta_x \\ L & \mathbf{v}_y & = & \delta_y \\ L & \mathbf{v}_z & = & \delta_z \end{matrix}$$

September 12, 2005

8/90

Basic properties

- $\text{rank}(L) = n - c$ ($n - 1$ for connected meshes)
- We can reconstruct the xyz geometry from δ up to translation

$$L\mathbf{x} = \begin{matrix} L & \mathbf{v}_x & = & \delta_x \\ 1 & & & c_x \\ L & \mathbf{v}_y & = & \delta_y \\ 1 & & & c_y \\ L & \mathbf{v}_z & = & \delta_z \\ 1 & & & c_z \end{matrix}$$

September 12, 2005

9/90

Reconstruction

$$\begin{matrix} L & \mathbf{v}_x & = & \delta_x \\ 1 & & & c_x \\ 1 & & & c_x \\ L & \mathbf{v}_y & = & \delta_y \\ 1 & & & c_y \\ 1 & & & c_y \\ L & \mathbf{v}_z & = & \delta_z \\ 1 & & & c_z \\ 1 & & & c_z \end{matrix}$$

September 12, 2005

10/90

Reconstruction

$$\begin{matrix} L & \mathbf{v}_x & = & \delta_x \\ 1 & & & c_x \\ 1 & & & c_x \end{matrix}$$

$$\tilde{\mathbf{x}} = \arg \min_{\mathbf{x}} \left(\|L\mathbf{x} - \delta_x\|^2 + \sum_{s=1}^k |x_s - c_s|^2 \right)$$

September 12, 2005

11/90

Reconstruction

$$\begin{matrix} L & \mathbf{v}_x & = & \delta_x \\ 1 & & & c_x \\ 1 & & & c_x \end{matrix}$$

$$A \mathbf{x} = \mathbf{b}$$

Normal Equations:

$$A^T A \mathbf{x} = A^T \mathbf{b}$$

$$\mathbf{x} = \underbrace{(A^T A)^{-1}}_{\text{compute once}} A^T \mathbf{b}$$

12/90

What we have so far

- Laplacian coordinates δ
 - Local representation
 - Translation-invariant
- Linear transition from δ to xyz
 - can constrain more than 1 vertex
 - least-squares solution

September 12,
2005

13/90

Editing using differential coordinates

- The editing process from the user's point of view:
 - 1) First, a ROI, anchors and a handle vertex should be set.
 - 2) Then the edit is Performed By moving this vertex.

Editing using differential coordinates

- The user moves the handle and **interactively** the surface changes.
- The stationary anchors are responsible for **smooth transition** of the edited part to the rest of the mesh.
- This is done using increasing weight with geodesic distance in the **soft** spatial equations.

Example

16/90

Is that the state of the art?

- Laplacians are translation invariant but **NOT** rotation invariant.

September 12,
2005

17/90

September 12,
2005

18/90

What else can we do with it?

- Membrane 2D (flattening), 3D Shape interpolation.
- Compact shape representation
 - Quantization
 - New bases for geometry rep.
- “Good” function basis over the surface.

September 12, 2005

19/90

Membrane surfaces

- Use zero Laplacians.

$$\begin{matrix}
 \text{L} \\
 \hline
 1 \\
 1 \\
 1
 \end{matrix}
 \mathbf{v} = \begin{matrix}
 \mathbf{0} \\
 \hline
 c_1 \\
 c_2 \\
 c_k
 \end{matrix}$$

In 2D:

Texture Mapping

[Piponi2000]

Geometrical function basis

- Harmonics: eigenfunctions of the Laplacian.

$$\frac{d^2}{d\theta^2} f(\theta) = \lambda f(\theta)$$

$$\begin{cases}
 f(\theta) = \sin(k\theta) \\
 f(\theta) = \cos(k\theta)
 \end{cases}$$

Good basis for function over the circle:

$$g(\theta) = A_0 + \sum_{k=1}^{\infty} A_n \cos(k\theta) + \sum_{k=1}^{\infty} B_n \sin(k\theta)$$

Geometrical function basis

- Spherical harmonics. $\Delta f = \lambda f$

Geometrical function basis

$$L \quad f = \lambda f$$

Correspondences between surfaces
