5.5 DATA COMPRESSION

- basics
- run-length coding
- **▶** Huffman compression
- **▶ LZW compression**

basics

- run-length coding
- ▶ Huffman compression
- ▶ LZW compression

Data compression

Compression reduces the size of a file:

- To save space when storing it.
- To save time when transmitting it.
- Most files have lots of redundancy.

Who needs compression?

- Moore's law: # transistors on a chip doubles every 18-24 months.
- Parkinson's law: data expands to fill space available.
- Text, images, sound, video, ...

"All of the books in the world contain no more information than is broadcast as video in a single large American city in a single year. Not all bits have equal value." — Carl Sagan

Basic concepts ancient (1950s), best technology recently developed.

Applications

Generic file compression.

• Files: GZIP, BZIP, 7z.

• Archivers: PKZIP.

• File systems: NTFS, HFS+, ZFS.

Multimedia.

• Images: GIF, JPEG.

• Sound: MP3.

Video: MPEG, DivX™, HDTV.

Communication.

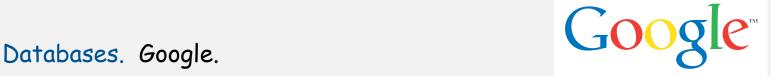

• ITU-T T4 Group 3 Fax.

V.42bis modem.

• Skype.

Lossless compression and expansion

Message. Binary data B we want to compress.

Compress. Generates a "compressed" representation C(B).

Expand. Reconstructs original bitstream B.

 $\begin{array}{c} \textbf{Compress} \\ \textbf{bitstream B} \\ \hline \textbf{0110110101} \\ \textbf{ } \\ \textbf{$

Compression ratio. Bits in C(B) / bits in B.

Ex. 50-75% or better compression ratio for natural language.

uses fewer bits (you hope)

Food for thought

Data compression has been omnipresent since antiquity:

- Number systems.
- Natural languages.
- Mathematical notation.

$$\iiint \qquad \sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{\pi^2}{6}$$

has played a central role in communications technology,

- Grade 2 Braille.
- Morse code.
- Telephone system.

b	r	a	i	I	I	е
• 0 • 0 0 0	• O • • O • O	• 0 0 0 0 0	<pre>0 • 0 0 0 0 0 0</pre>	• 0 • 0 • 0	• 0 • 0 • 0 0 0	• O O O O
but	rather	a	I	like	like	every

and is part of modern life.

- MP3.
- MPEG.

Data representation: genomic code

Genome. String over the alphabet { A, C, T, G }.

Goal. Encode an N-character genome: ATAGATGCATAG...

Standard ASCII encoding.

- 8 bits per char.
- 8 N bits.

char	hex	binary
A	41	01000001
С	43	01000011
T	54	01010100
G	47	01000111

Two-bit encoding.

- 2 bits per char.
- 2 N bits.

char	binary
A	00
С	01
T	10
G	11

Amazing but true. Initial genomic databases in 1990s did not use such a code! Fixed-length code. k-bit code supports alphabet of size 2^k .

Reading and writing binary data

Binary standard input and standard output. Libraries to read and write bits from standard input and to standard output.

```
public class BinaryStdIn

boolean readBoolean() read 1 bit of data and return as a boolean value

char readChar() read 8 bits of data and return as a char value

char readChar(int r) read r bits of data and return as a char value

[similar methods for byte (8 bits); short (16 bits); int (32 bits); long and double (64 bits)]

boolean isEmpty() is the bitstream empty?

void close() close the bitstream
```

```
public class BinaryStdOut

void write(boolean b) write the specified bit

void write(char c) write the specified 8-bit char

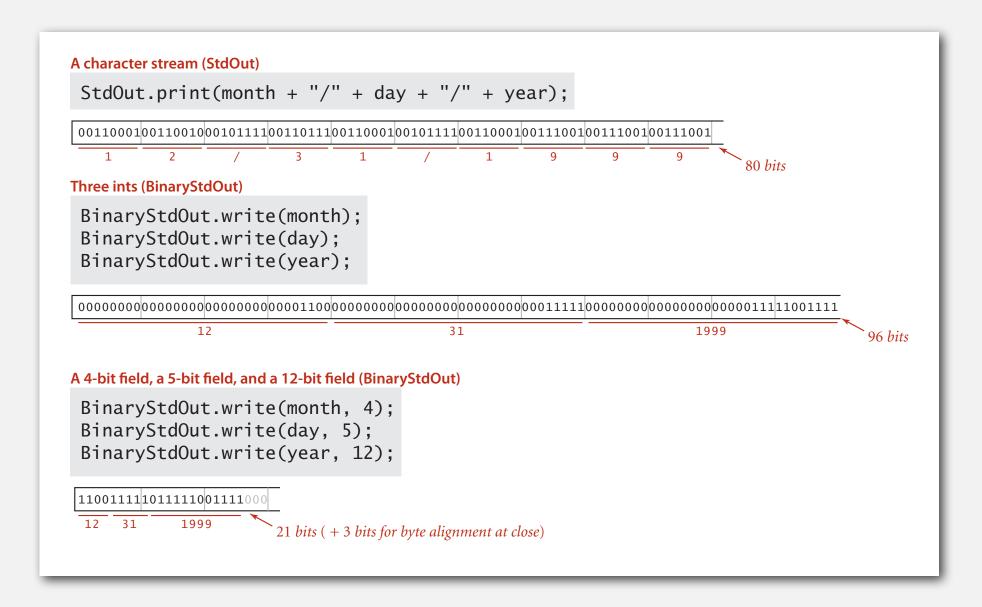

void write(char c, int r) write the r least significant bits of the specified char

[similar methods for byte (8 bits); short (16 bits); int (32 bits); long and double (64 bits)]

void close() close the bitstream
```

Writing binary data

Date representation. Three different ways to represent 12/31/1999.

Binary dumps

Q. How to examine the contents of a bitstream?

Standard character stream

% more abra.txt
ABRACADABRA!

Bitstream represented as 0 and 1 characters

Bitstream represented with hex digits

% java HexDump 4 < abra.txt
41 42 52 41
43 41 44 41
42 52 41 21
12 bytes</pre>

Bitstream represented as pixels in a Picture

% java PictureDump 16 6 < abra.txt

16-by-6 pixel window, magnified

96 bits

	Hexadecimal to ASCII conversion table															

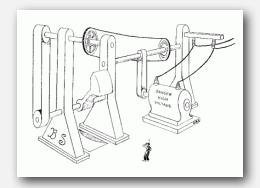

Universal data compression

US Patent 5,533,051 on "Methods for Data Compression", which is capable of compression all files.

Slashdot reports of the Zero Space TunerTM and BinaryAcceleratorTM.

"ZeoSync has announced a breakthrough in data compression that allows for 100:1 lossless compression of random data. If this is true, our bandwidth problems just got a lot smaller...."

Physical analog. Perpetual motion machines.

Gravity engine by Bob Schadewald

Universal data compression

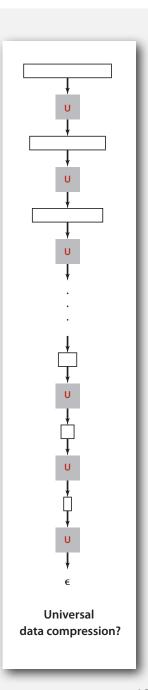

Proposition. No algorithm can compress every bitstring.

Pf 1. [by contradiction]

- Suppose you have a universal data compression algorithm ${\cal U}$ that can compress every bitstream.
- Given bitstring B_0 , compress it to get smaller bitstring B_1 .
- Compress B_1 to get a smaller bitstring B_2 .
- Continue until reaching bitstring of size 0.
- Implication: all bitstrings can be compressed to 0 bits!

Pf 2. [by counting]

- Suppose your algorithm that can compress all 1,000-bit strings.
- 2^{1000} possible bitstrings with 1,000 bits.
- Only $1 + 2 + 4 + ... + 2^{998} + 2^{999}$ can be encoded with ≤ 999 bits.
- Similarly, only 1 in 2^{499} bitstrings can be encoded with ≤ 500 bits!

Undecidability

```
% java RandomBits | java PictureDump 2000 500
```

A difficult file to compress: one million (pseudo-) random bits

```
public class RandomBits
{
    public static void main(String[] args)
    {
        int x = 11111;
        for (int i = 0; i < 1000000; i++)
        {
            x = x * 314159 + 218281;
            BinaryStdOut.write(x > 0);
        }
        BinaryStdOut.close();
    }
}
```

Rdenudcany in Enlgsih Inagugae

Q. How much redundancy is in the English language?

"... randomising letters in the middle of words [has] little or no effect on the ability of skilled readers to understand the text. This is easy to denmtrasote. In a pubiltacion of New Scnieitst you could ramdinose all the letetrs, keipeng the first two and last two the same, and reibadailty would hadrly be aftefeed. My ansaylis did not come to much beucase the thoery at the time was for shape and senquece retigcionon. Saberi's work sugsegts we may have some pofrweul palrlael prsooscers at work. The resaon for this is suerly that idnetiying coentnt by paarllel prseocsing speeds up regnicoiton. We only need the first and last two letetrs to spot chganes in meniang." — *Graham Rawlinson*

A. Quite a bit.

- run-length codingHuffman compression

Run-length encoding

Simple type of redundancy in a bitstream. Long runs of repeated bits.

Representation. Use 4-bit counts to represent alternating runs of 0s and 1s: 15 0s, then 7 1s, then 7 0s, then 11 1s.

$$\frac{1111}{15} \frac{0111}{7} \frac{0111}{7} \frac{1011}{11}$$
 16 bits (instead of 40)

- Q. How many bits to store the counts?
- A. We'll use 8.
- Q. What to do when run length exceeds max count?
- A. If longer than 255, intersperse runs of length 0.

Applications. JPEG, ITU-T T4 Group 3 Fax, ...

Run-length encoding: Java implementation

```
public class RunLength
                                                            run-length limit
   private final static int R = 256;
                                                            (needed for compress)
   private final static int lgR = 8;
   public static void compress()
   { /* see textbook */ }
   public static void expand()
      boolean b = false;
      while (!BinaryStdIn.isEmpty())
                                                            read 8-bit count from standard input
          int run = BinaryStdIn.readInt(lgR);
          for (int i = 0; i < run; i++)
             BinaryStdOut.write(b);
                                                           write 1 bit to standard output
          b = !b;
       }
                                                            pads 0s for byte alignment
      BinaryStdOut.close();
```

An application: compress a bitmap

Typical black-and-white-scanned image.

- 300 pixels/inch.
- 8.5-by-11 inches.
- $300 \times 8.5 \times 300 \times 11 = 8.415$ million bits.

Observation. Bits are mostly white.

Typical amount of text on a page.

40 lines \times 75 chars per line = 3,000 chars.

```

David Huffman

Variable-length codes

Use different number of bits to encode different chars.

Variable-length codes

- Q. How do we avoid ambiguity?
- A. Ensure that no codeword is a prefix of another.
- Ex 1. Fixed-length code.
- Ex 2. Append special stop char to each codeword.
- Ex 3. General prefix-free code.

```
Codeword table

key value
! 101
A 0
B 1111
C 110
D 100
R 1110

Compressed bitstring
0111111100110010001111111100101 ← 30 bits
A B RA CA DA B RA !
```

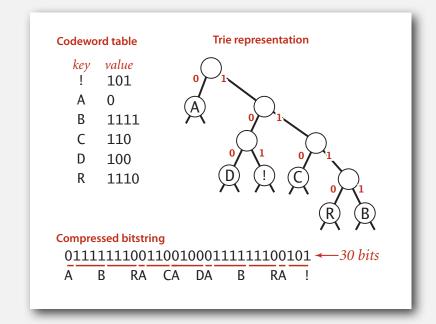

```
Codeword table

C 010
D 100
R 011

Compressed bitstring
1100011110101110011111111 ← 29 bits
A B R A C A D A B R A !
```

Prefix-free codes: trie representation

- Q. How to represent the prefix-free code?
- A. A binary trie!
- · Chars in leaves.
- Codeword is path from root to leaf.

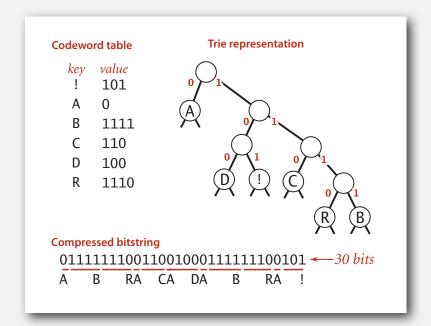

Prefix-free codes: compression and expansion

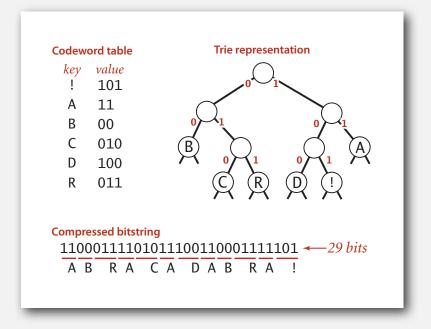

Compression.

- Method 1: start at leaf; follow path up to the root; print bits in reverse.
- Method 2: create ST of key-value pairs.

Expansion.

- Start at root.
- Go left if bit is 0; go right if 1.
- If leaf node, print char and return to root.

Huffman trie node data type

```
private static class Node implements Comparable<Node>
   private char ch; // Unused for internal nodes.
   private int freq; // Unused for expand.
   private final Node left, right;
   public Node(char ch, int freq, Node left, Node right)
      this.ch = ch:
      this.freq = freq;
                                                                  initializing constructor
      this.left = left;
      this.right = right;
   public boolean isLeaf()
                                                                  is Node a leaf?
   { return left == null && right == null; }
                                                                  compare Nodes by frequency
   public int compareTo(Node that)
                                                                  (stay tuned)
   { return this.freq - that.freq; }
```

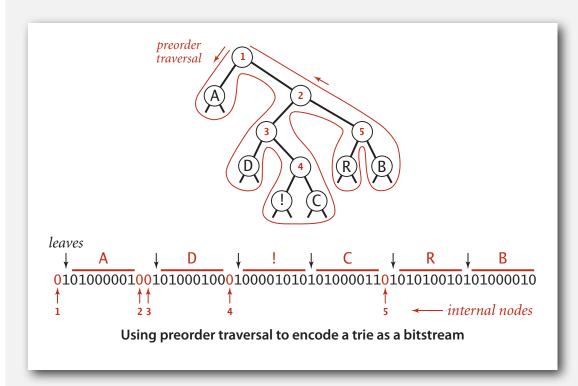

Prefix-free codes: expansion

```
public void expand()
                                                      read in encoding trie
   Node root = readTrie();
                                                      read in number of chars
   int N = BinaryStdIn.readInt();
   for (int i = 0; i < N; i++)
      Node x = root;
                                                      expand codeword for ith char
      while (!x.isLeaf())
      {
          if (!BinaryStdIn.readBoolean())
             x = x.left;
         else
             x = x.right;
      BinaryStdOut.write(x.ch, 8);
   BinaryStdOut.close();
```

Running time. Linear in input size N (constant amount of work per bit read).

Prefix-free codes: how to transmit

- Q. How to write the trie?
- A. Write preorder traversal of trie; mark leaf and internal nodes with a bit.

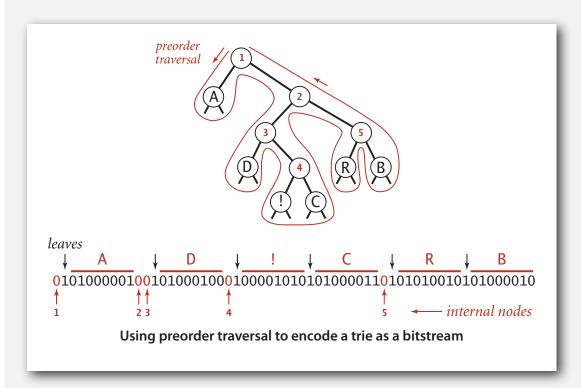

```
private static void writeTrie(Node x)
{
    if (x.isLeaf())
    {
        BinaryStdOut.write(true);
        BinaryStdOut.write(x.ch, 8);
        return;
    }
    BinaryStdOut.write(false);
    writeTrie(x.left);
    writeTrie(x.right);
}
```

Note. If message is long, overhead of transmitting trie is small.

Prefix-free codes: how to transmit

- Q. How to read in the trie?
- A. Reconstruct from preorder traversal of trie.

```
private static Node readTrie()
{
    if (BinaryStdIn.readBoolean())
    {
        char c = BinaryStdIn.readChar(8);
        return new Node(c, 0, null, null);
    }
    Node x = readTrie();
    Node y = readTrie();
    return new Node('\0', 0, x, y);
}
    not used
```

Shannon-Fano codes

Q. How to find best prefix-free code?

Shannon-Fano algorithm:

- Partition symbols S into two subsets S_0 and S_1 of (roughly) equal frequency.
- Codewords for symbols in S_0 start with 0; for symbols in S_1 start with 1.
- Recur in S_0 and S_1 .

char	freq	encoding
A	5	0
С	1	0

 $S_0 = codewords starting with 0$

char	freq	encoding
В	2	1
D	1	1
R	2	1
!	1	1

 $S_1 = codewords starting with 1$

Problem 1. How to divide up symbols?

Problem 2. Not optimal!

Huffman codes

Q. How to find best prefix-free code?

Huffman algorithm:

- Count frequency freq[i] for each char i in input.
- Start with one node corresponding to each char i (with weight freq[i]).
- Repeat until single trie formed:
 - select two tries with min weight freq[i] and freq[j]
 - merge into single trie with weight freq[i] + freq[j]

Applications:

Constructing a Huffman encoding trie demo

Constructing a Huffman encoding trie: Java implementation

```
private static Node buildTrie(int[] freq)
    MinPQ<Node> pq = new MinPQ<Node>();
    for (char i = 0; i < R; i++)
                                                                        initialize PQ with
       if (freq[i] > 0)
                                                                        singleton tries
          pq.insert(new Node(i, freq[i], null, null));
    while (pq.size() > 1)
                                                                        merge two
                                                                        smallest tries
       Node x = pq.delMin();
       Node y = pq.delMin();
       Node parent = new Node('\0', x.freq + y.freq, x, y);
       pq.insert(parent);
    return pq.delMin();
                               not used
                                         total frequency two subtries
}
```

Huffman encoding summary

Proposition. [Huffman 1950s] Huffman algorithm produces an optimal prefix-free code.

Pf. See textbook.

no prefix-free code uses fewer bits

Implementation.

- Pass 1: tabulate char frequencies and build trie.
- Pass 2: encode file by traversing trie or lookup table.

Q. Can we do better? [stay tuned]

- ▶ basics
- run-length coding
- ➤ Huffman compression
- **▶ LZW compression**

Abraham Lempel Jacob Ziv

Statistical methods

Static model. Same model for all texts.

- Fast.
- Not optimal: different texts have different statistical properties.
- Ex: ASCII, Morse code.

Dynamic model. Generate model based on text.

- Preliminary pass needed to generate model.
- Must transmit the model.
- Ex: Huffman code.

Adaptive model. Progressively learn and update model as you read text.

- More accurate modeling produces better compression.
- Decoding must start from beginning.
- Ex: LZW.

Lempel-Ziv-Welch compression

LZW compression.

- Create ST associating W-bit codewords with string keys.
- Initialize ST with codewords for single-char keys.
- Find longest string s in ST that is a prefix of unscanned part of input.
- Write the W-bit codeword associated with s.

• Add s + c to ST, where c is next char in the input.

longest prefix match

LZW compression: Java implementation

```
public static void compress()
  String input = BinaryStdIn.readString();
                                                                      read in input as a string
   TST<Integer> st = new TST<Integer>();
                                                                      codewords for single-
   for (int i = 0; i < R; i++)
                                                                      char, radix R keys
        st.put("" + (char) i, i);
   int code = R+1;
   while (input.length() > 0)
                                                                      find longest prefix match s
       String s = st.longestPrefixOf(input);
                                                                      write W-bit codeword for s
       BinaryStdOut.write(st.get(s), W);
       int t = s.length();
       if (t < input.length() && code < L)</pre>
           st.put(input.substring(0, t+1), code++);
                                                                      add new codeword
       input = input.substring(t);
                                                                      scan past s in input
   BinaryStdOut.write(R, W);
                                                                      write last codeword
                                                                      and close input stream
   BinaryStdOut.close();
```

ABSTRACT

A data compressor compresses an input stream of data character signals by storing in a string table strings of data character signals encountered in the input stream. The compressor searches the input stream to determine the longest match to a stored string. Each stored string comprises a prefix string and an extension character where the extension character is the last character in the string and the prefix string comprises all but the extension character. Each string has a code signal associated therewith and a string is stored in the string table by, at least implicitly, storing the code signal for the string, the code signal for the string prefix and the extension character. When the longest match between the input data character stream and the stored strings is determined, the code signal for the longest match is transmitted as the compressed code signal for the encountered string of characters and an extension string is stored in the string table. The prefix of the extended string is the longest match and the extension character of the extended string is the next input data character signal following the longest match. Searching through the string table and entering extended strings therein is effected by a limited search hashing procedure. Decompression is effected by a decompressor that receives the compressed code signals and generates a string table similar to that constructed by the compressor to effect lookup of received code signals so as to recover the data character signals comprising a stored string. The decompressor string table is updated by storing a string having a prefix in accordance with a prior received code signal and an extension character in accordance with the first character of the currently recovered string.

Data compression summary

Lossless compression.

- Represent fixed-length symbols with variable-length codes. [Huffman]
- Represent variable-length symbols with fixed-length codes. [LZW]

Lossy compression. [not covered in this course]

- JPEG, MPEG, MP3, ...
- FFT, wavelets, fractals, ...

Theoretical limits on compression. Shannon entropy.

Practical compression. Use extra knowledge whenever possible.
