

# COS 318: Operating Systems

## Non-Preemptive and Preemptive Threads

Kai Li

Computer Science Department

Princeton University

(<http://www.cs.princeton.edu/courses/cos318/>)

# Today's Topics

---

- ◆ Non-preemptive threads
- ◆ Preemptive threads
- ◆ Kernel vs. user threads
- ◆ Too much milk problem

# Revisit Monolithic OS Structure

- ◆ Kernel has its address space shared with all processes
- ◆ Kernel consists of
  - Boot loader
  - BIOS
  - Key drivers
  - Threads
  - Scheduler
- ◆ Scheduler
  - Use a ready queue to hold all ready threads
  - Schedule in the same address space (thread context switch)
  - Schedule in a new address space (process context switch)

# Non-Preemptive Scheduling

# Scheduler

---

- ◆ A non-preemptive scheduler invoked by calling
  - `block()`
  - `yield()`

- ◆ The simplest form

Scheduler:

**save current process/thread state**

**choose next process/thread to run**

**dispatch (load PCB/TCB and jump to it)**

- ◆ Does this work?

# More on Scheduler

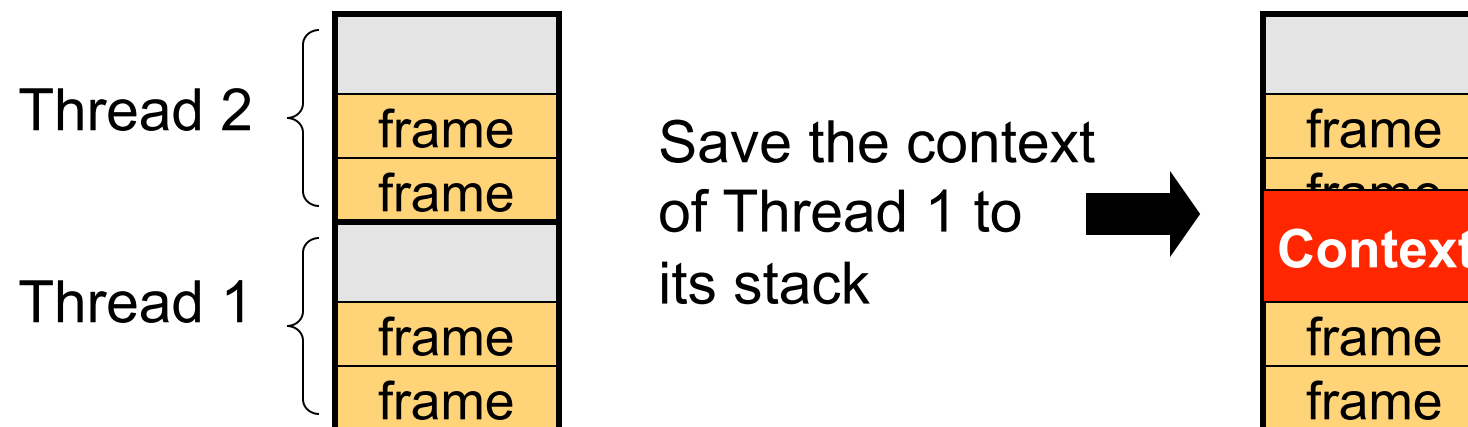

---

- ◆ Should the scheduler use a special stack?
- ◆ Should the scheduler simply be a kernel thread?

# Where and How to Save Thread Context?

- ◆ Save the context on the thread's stack
  - Many processors have a special instruction to do it efficiently
  - But, need to deal with the overflow problem
- ◆ Check before saving
  - Make sure that the stack has no overflow problem
  - Copy it to the TCB residing in the kernel heap
  - Not so efficient, but no overflow problems

# Preemption by I/O and Timer Interrupts

## ◆ Why

- Timer interrupt to help CPU management
- Asynchronous I/O to overlap with computation

## ◆ Interrupts

- Between instructions
- Within an instruction except atomic ones

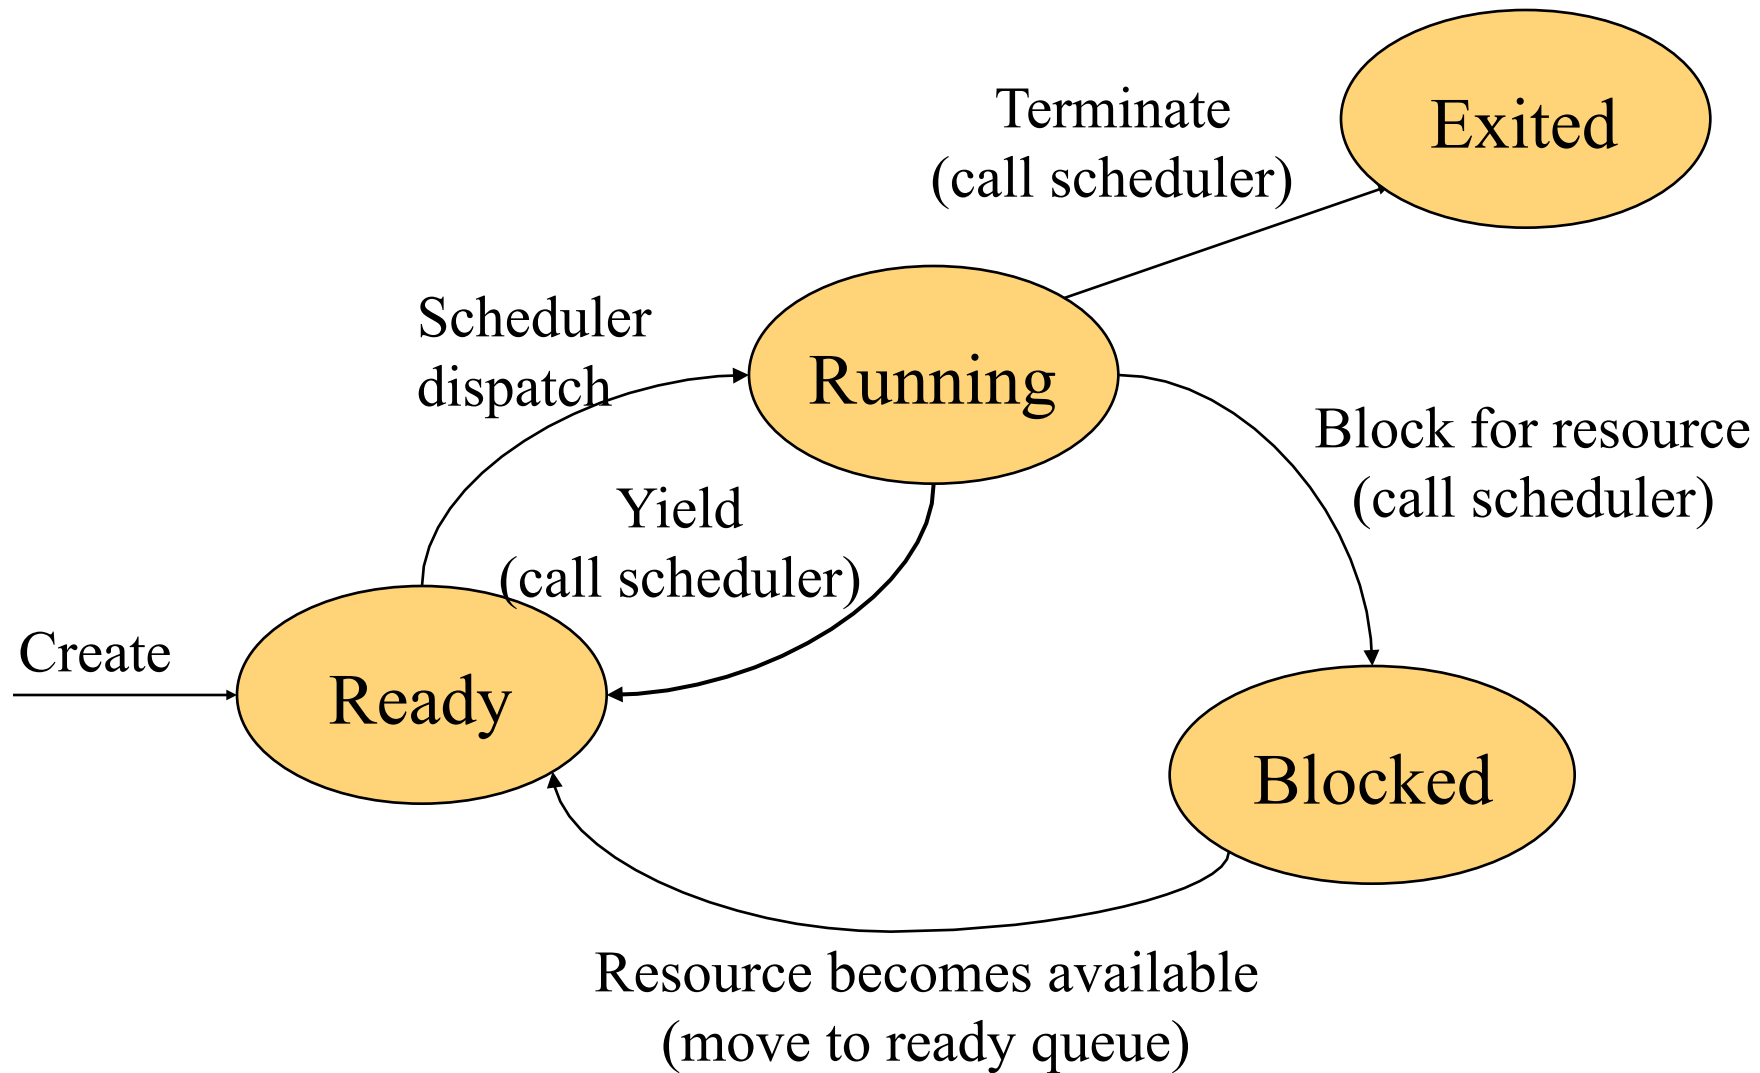

## ◆ Manipulate interrupts

- Disable (mask) interrupts
- Enable interrupts
- Non-Masking Interrupts

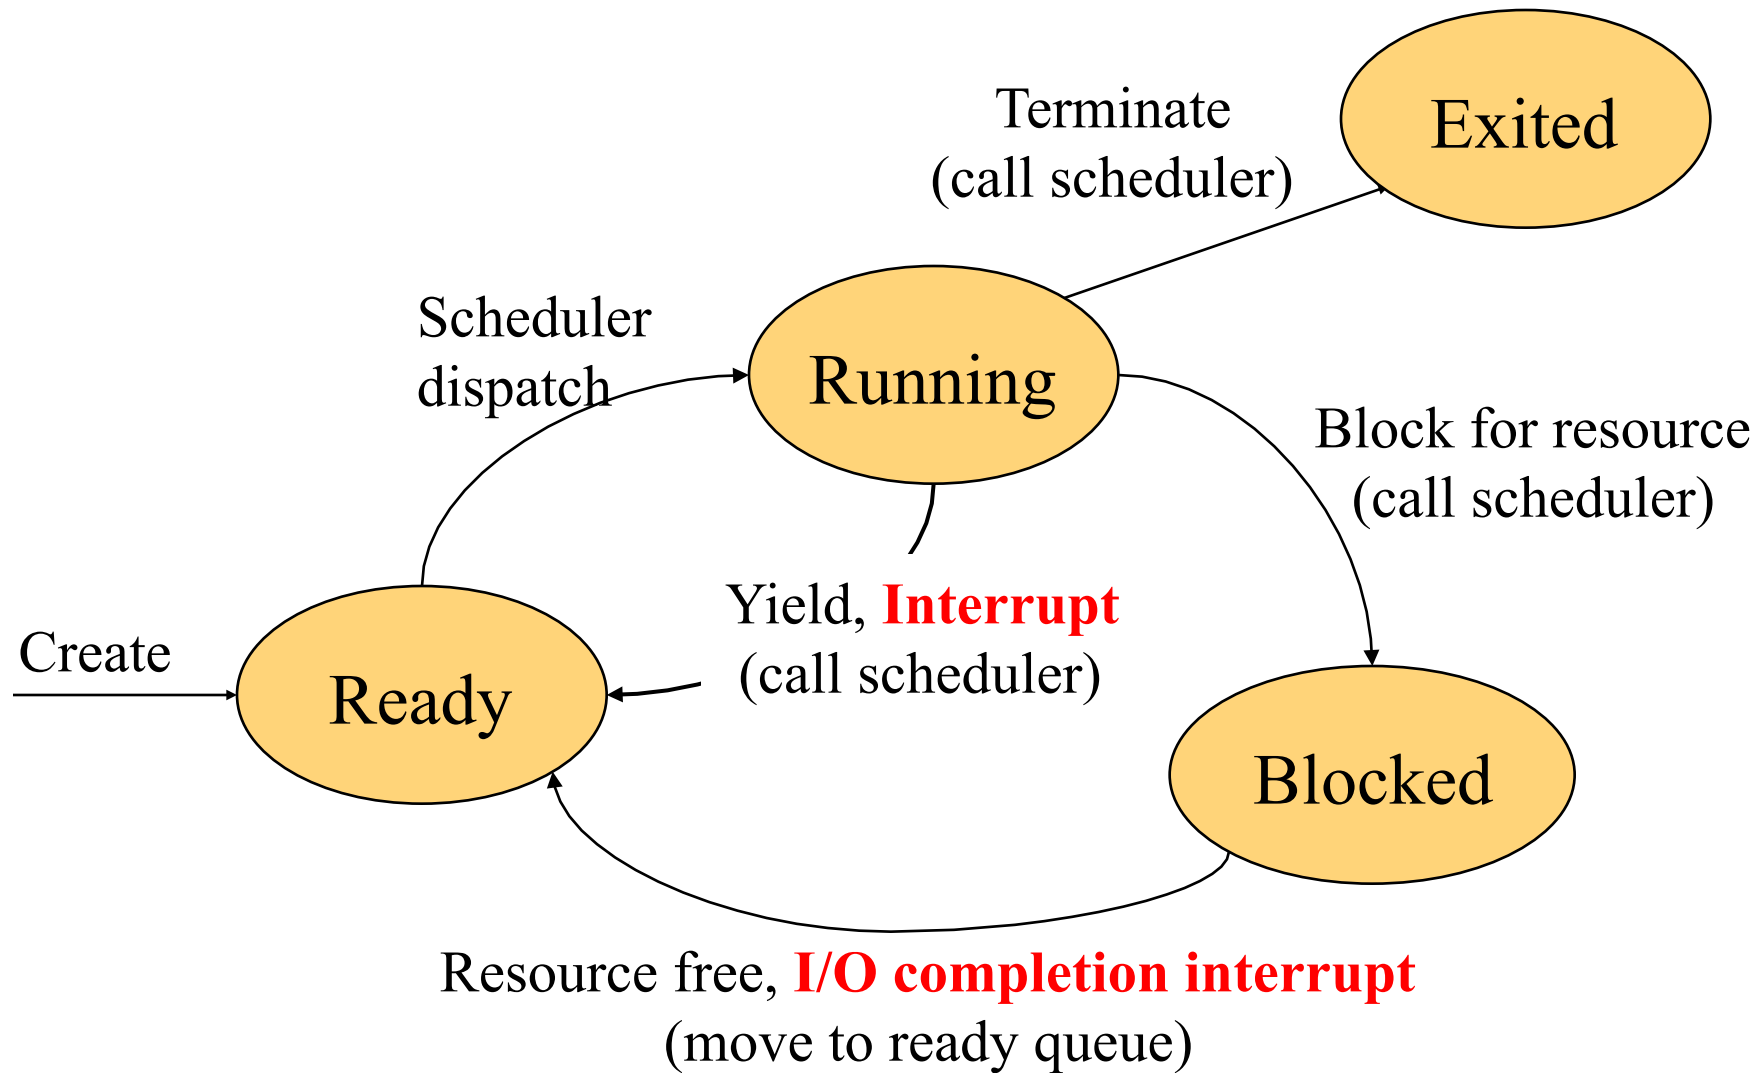

# State Transition for Non-Preemptive Scheduling

# State Transition for Preemptive Scheduling

# Interrupt Handling for Preemptive Scheduling

---

- ◆ Timer interrupt handler:
  - Save the current process / thread to its PCB / TCB
  - ... (What to do here?)
  - Call scheduler
- ◆ Other interrupt handler:
  - Save the current process / thread to its PCB / TCB
  - Do the I/O job
  - Call scheduler
- ◆ Issues
  - Disable/enable interrupts
  - Make sure that it works on multiprocessors

# Dealing with Preemptive Scheduling

## ◆ Problem

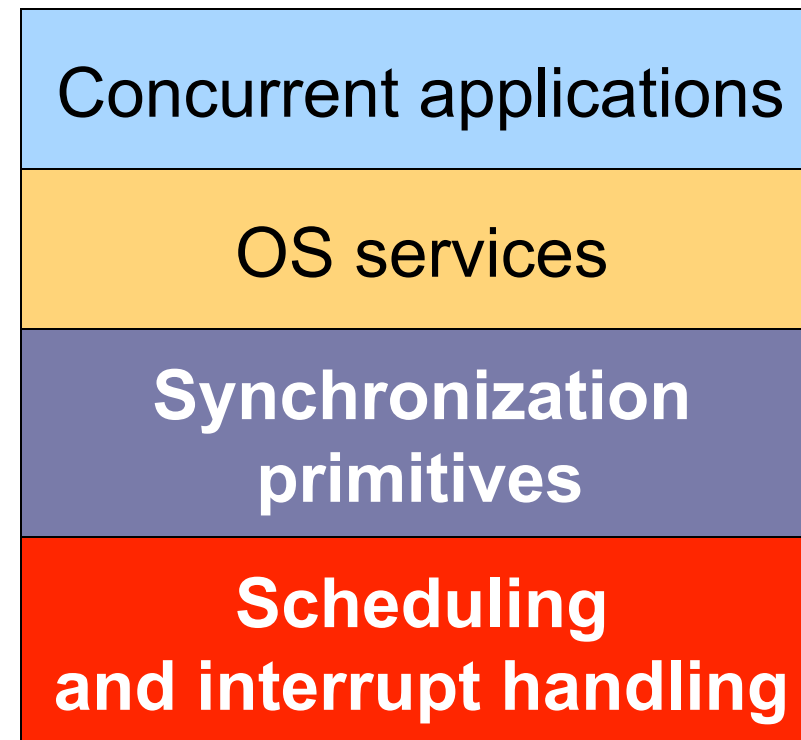

- Interrupts can happen anywhere

## ◆ An obvious approach

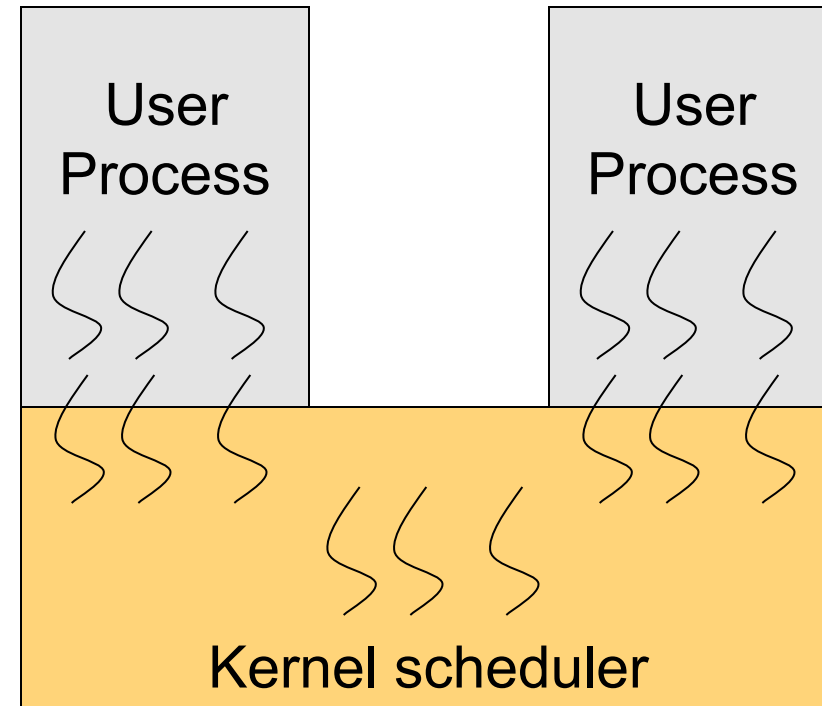

- Worry about interrupts and preemptions all the time

## ◆ What we want

- Worry less all the time
- Low-level behavior encapsulated in “primitives”
- Synchronization primitives worry about preemption
- OS and applications use synchronization primitives

# User Threads vs. Kernel Threads

- ◆ Context switch at user-level without a system call (Java threads)
- ◆ Is it possible to do preemptive scheduling?
- ◆ What about I/O events?

- ◆ A user thread
  - Makes a system call (e.g. I/O)
  - Gets interrupted
- ◆ Context switch in the kernel

# Summary of User vs. Kernel Threads

---

## ◆ User-level threads

- User-level thread package implements thread context switches using codes like co-routines
- Timer interrupt (signal facility) can introduce preemption
- When a user-level thread is blocked on an I/O event, the whole process is blocked

## ◆ Kernel-threads

- Kernel-level threads are scheduled by a kernel scheduler
- A context switch of kernel-threads is more expensive than user threads due to crossing protection boundaries

## ◆ Hybrid

- It is possible to have a hybrid scheduler, but it is complex

# Interactions between User and Kernel Threads

- ◆ Two approaches
  - Each user thread has its own kernel stack
  - All threads of a process share the same kernel stack

	Private kernel stack	Shared kernel stack
Memory usage	More	Less
System services	Concurrent access	Serial access
Multiprocessor	Yes	Not within a process
Complexity	More	Less

# “Too Much Milk” Problem

- ◆ Do not want to buy too much milk
- ◆ Any person can be distracted at any point

	Student A	Student B
15:00	Look at fridge: out of milk	
15:05	Leave for Wawa	
15:10	Arrive at Wawa	Look at fridge: out of milk
15:15	Buy milk	Leave for Wawa
15:20	Arrive home; put milk away	Arrive at Wawa
15:25		Buy milk
		Arrive home; put milk away Oh No!

# Using A Note?

## Thread A

```
if ( noMilk ) {  
    if (noNote) {  
        leave note;  
        buy milk;  
        remove note;  
    }  
}
```

## Thread B

```
if ( noMilk ) {  
    if (noNote) {  
        leave note;  
        buy milk;  
        remove note;  
    }  
}
```

- ◆ Any issue with this approach?

# Another Possible Solution?

## Thread A

```
leave noteA
if (noNoteB) {
  if (noMilk)
    buy milk
}
remove noteA
```

**Didn't buy milk**

## Thread B

```
leave noteB
if (noNoteA)
  if (noMilk)
    buy milk
}
remove noteB
```

**Didn't buy milk**

- ◆ Does this method work?

# Yet Another Possible Solution?

---

## Thread A

```
leave noteA
while (noteB)
    do nothing;
if (noMilk)
    buy milk;
remove noteA
```

## Thread B

```
leave noteB
if (noNoteA) {
    if (noMilk) {
        buy milk
    }
}
remove noteB
```

- ◆ Would this fix the problem?

# Remarks

---

- ◆ The last solution works, but
  - Life is too complicated
  - A's code is different from B's
  - Busy waiting is a waste
- ◆ Peterson's solution is also complex
- ◆ What we want is:

```
Acquire(lock) ;  
if (noMilk)  
    buy milk ;  
Release(lock) ;
```

**Critical section**

# What Is A Good Solution

---

- ◆ Only one process/thread inside a critical section
- ◆ No assumption about CPU speeds
- ◆ A process/thread inside a critical section should not be blocked by any process outside the critical section
- ◆ No one waits forever
  
- ◆ Works for multiprocessors
- ◆ Same code for all processes/threads

# Summary

---

- ◆ Non-preemptive threads issues
  - Scheduler
  - Where to save contexts
- ◆ Preemptive threads
  - Interrupts can happen any where!
- ◆ Kernel vs. user threads
  - Main difference is which scheduler to use
- ◆ Too much milk problem
  - What we want is mutual exclusion
