10. Creating Data Types

- Overview
- Point charges
- Turtle graphics
- Complex numbers

Object-oriented programming (OOP)

Object-oriented programming (OOP).

- Create your own data types (sets of values and ops on them).
- Use them in your programs (manipulate *objects*).

An **object** holds a data type value.
Variable names refer to objects.

<i>data type</i>	<i>set of values</i>	<i>examples of operations</i>
Color	three 8-bit integers	get red component, brighten
Picture	2D array of colors	get/set color of pixel (i, j)
String	sequence of characters	length, substring, compare

An **abstract data type** is a data type whose representation is *not specified*.

Impact: We can use ADTs without knowing implementation details.

- Previous lecture: how to write client programs for several useful ADTs
- This lecture: how to implement your own ADTs

Implementing a data type

To **create** a data type, you need provide code that

- Defines the set of values (**instance variables**).
- Implements operations on those values (**methods**).
- Creates and initialize new objects (**constructors**).

Instance variables

- Declarations associate variable names with types.
- Set of type values is "set of values".

Methods

- Like static methods.
- Can refer to instance variables.

Constructors

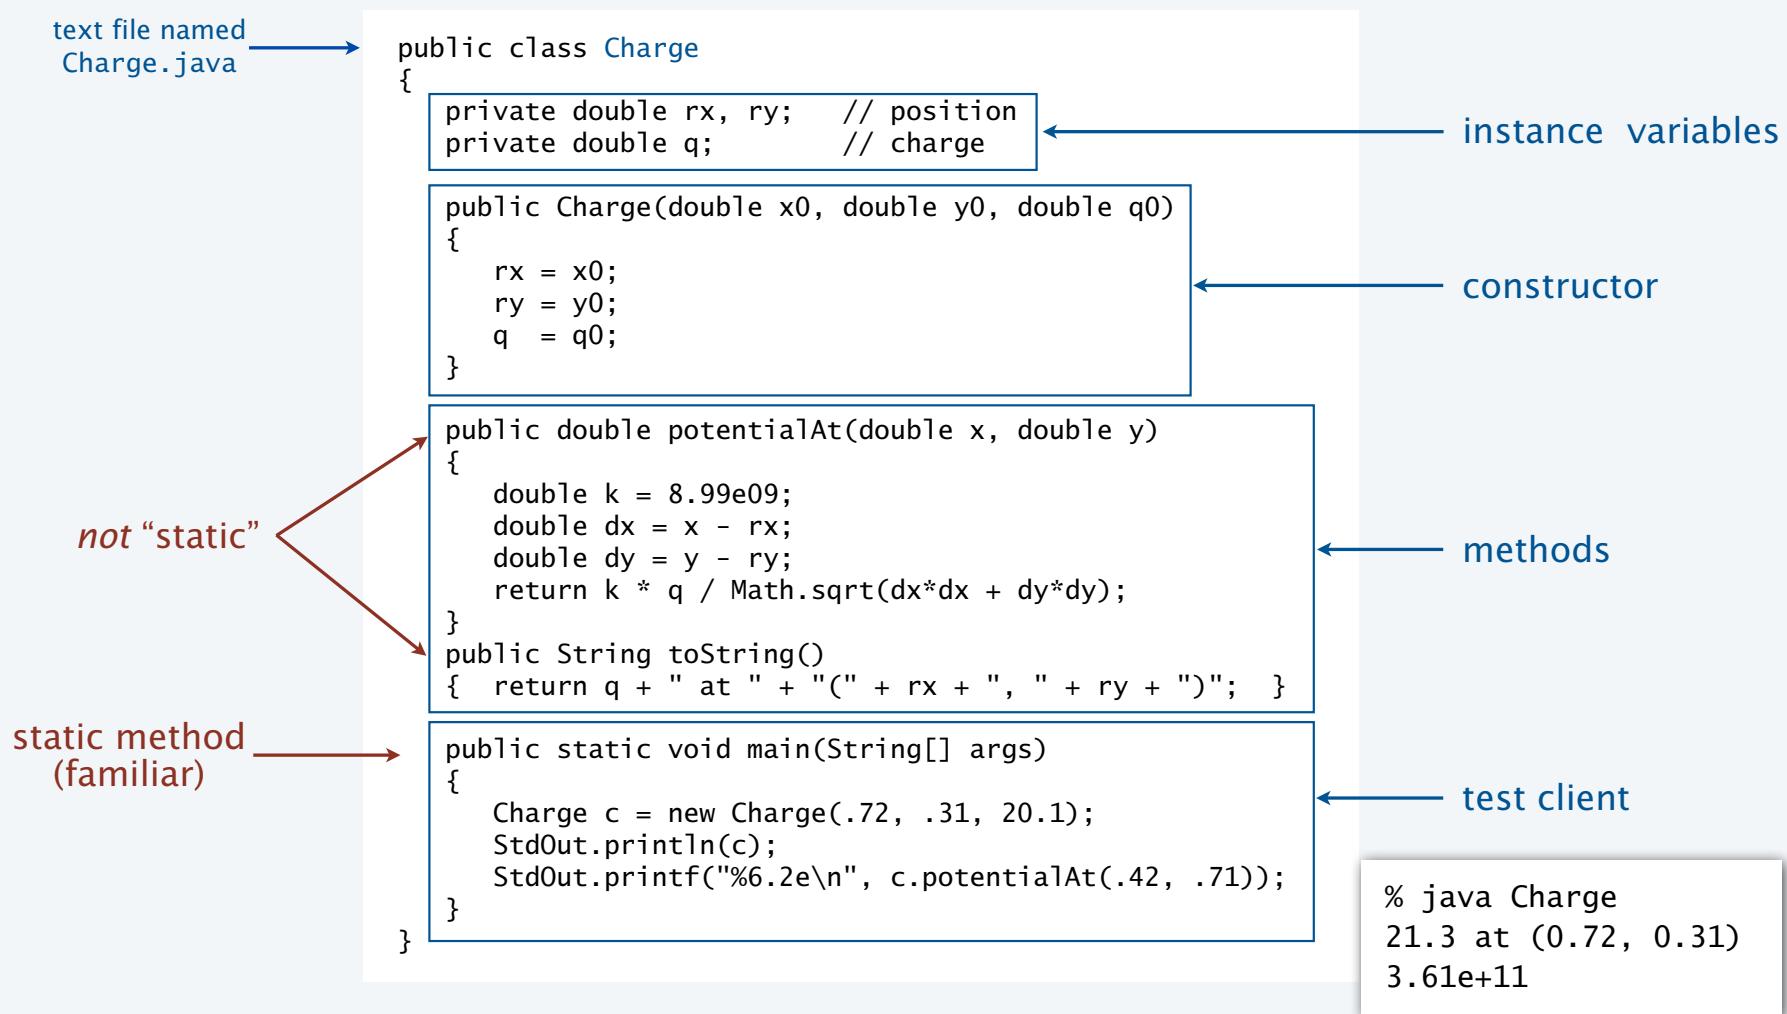

- Methods with the same name as the type.
- No return type declaration.
- Invoked by new, returns object of the type.

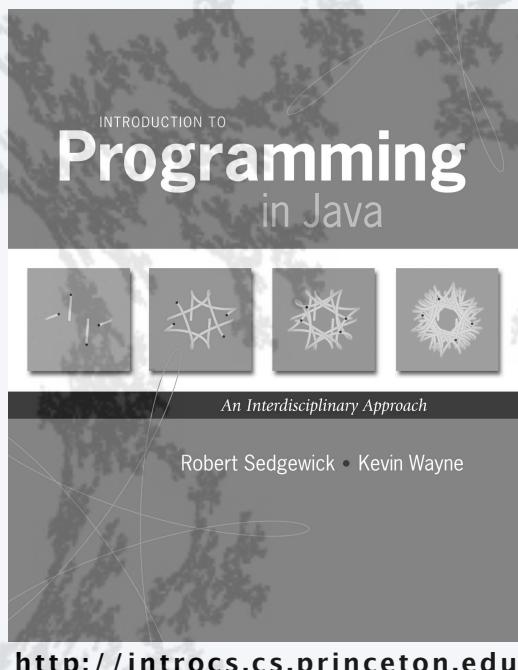

In Java, a data-type implementation is known as a **class**.

A Java class

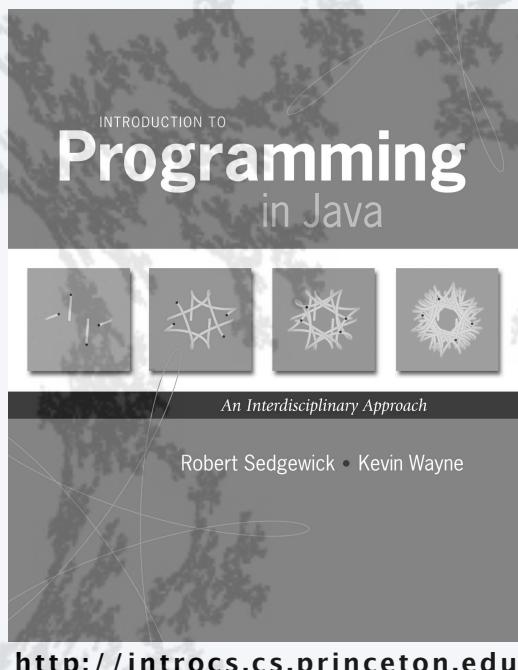

Anatomy of a Class

10. Creating Data Types

- Overview
- Point charges
- Turtle graphics
- Complex numbers

ADT for point charges

A **point charge** is an idealized model of a particle that has an electric charge.

An **ADT** allows us to write Java programs that manipulate point charges.

Values	<i>examples</i>		
	position (x, y)	(.53, .63)	(.13, .94)
electrical charge	21.3	81.9	

API (operations)	public class Charge	
	Charge(double x0, double y0, double q0)	
	double potentialAt(double x, double y)	<i>electric potential at (x, y) due to charge</i>
	String toString()	<i>string representation of this charge</i>

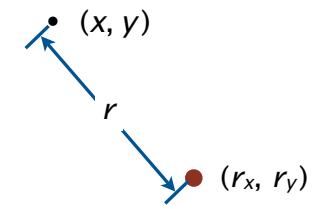

Crash course on electric potential

Electric potential is a measure of the effect of a point charge on its surroundings.

- It *increases* in proportion to the charge value.
- It *decreases* in proportion to the *inverse of the distance* from the charge.

Mathematically,

- Suppose a point charge c is located at (r_x, r_y) and has charge q .
- Let r be the distance between (x, y) and (r_x, r_y)
- Let $V_c(x, y)$ be the potential at (x, y) due to c .
- Then
$$V_c(x, y) = k \frac{q}{r}$$
 where $k = 8.99 \times 10^9$ is a normalizing factor.

Q. What happens when multiple charges are present?

A. The potential at a point is the *sum* of the potentials due to the individual charges.

Note: Similar laws hold in many other situations.

← Example. *N*-body (an inverse *square* law).

Point charge implementation: Test client

Best practice. Begin by implementing a simple test client.

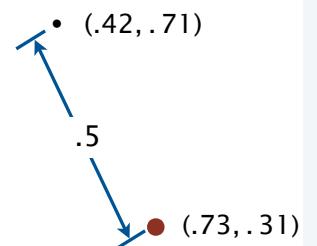

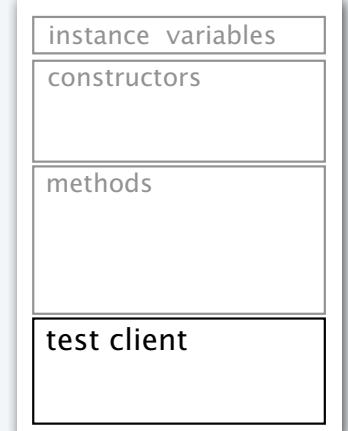

```
public static void main(String[] args)
{
    Charge c = new Charge(.72, .31, 20.1);
    StdOut.println(c);
    StdOut.printf("%6.2e\n", c.potentialAt(.42, .71));
}
```

$$V_c(x, y) = k \frac{q}{r}$$

$$\begin{aligned} r &= \sqrt{(r_x - x)^2 + (r_y - y)^2} \\ &= \sqrt{.3^2 + .4^2} = .5 \\ V_c(.42, .71) &= 8.99 \times 10^9 \frac{20.1}{.5} \\ &= 3.6 \times 10^{11} \end{aligned}$$

```
% java Charge
21.3 at (0.72, 0.31)
3.61e+11
```

← What we *expect*, once the implementation is done.

Point charge implementation: Instance variables

Instance variables define data-type values.

Values	examples		
	position (x, y)	(.53, .63)	(.13, .94)
electrical charge	21.3	81.9	

```
public class Charge
{
    private final double rx, ry;
    private final double q;
    ...
}
```

Modifiers control access.

- **private** denies clients access and therefore makes data type abstract.
- **final** disallows any change in value and therefore makes variable *immutable*.

↑
stay tuned

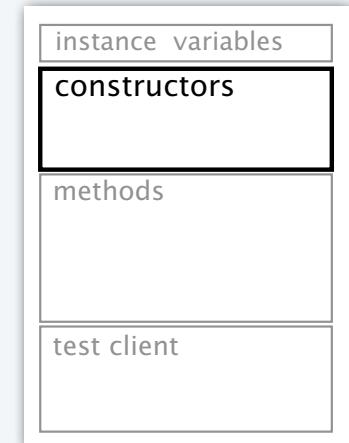

Key to OOP. Each *object* has instance-variable values.

Point charge implementation: Constructor

Constructors create and initialize new objects.

```
public class Charge
{
    ...
    public Charge(double x0, double y0, double q0)
    {
        rx = x0;
        ry = y0;
        q   = q0;
    }
    ...
}
```

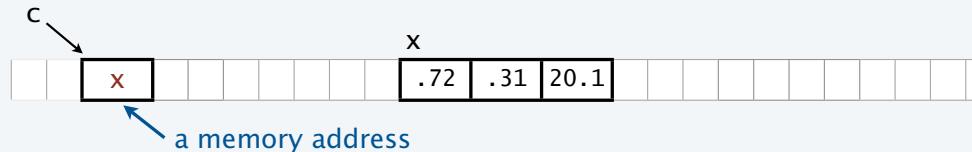

references to instance variables, which
are *not* declared within the constructor

Clients use `new` to invoke constructors.

- Pass arguments as in a method call.
- Return value is reference to new object.

Possible memory representation of
Charge c = new Charge(.72, .31, 20.1);

Point charge implementation: Methods

Methods define data-type operations (implement APIs).

API

public class Charge	
Charge(double x0, double y0, double q0)	
double potentialAt(double x, double y)	<i>electric potential at (x, y) due to charge</i>
String toString()	<i>string representation of this charge</i>

```
public class Charge
{
    ...
    public double potentialAt(double x, double y)
    {
        double k = 8.99e09;
        double dx = x - rx;
        double dy = y - ry;
        return k * q / Math.sqrt(dx*dx + dy*dy);
    }

    public String toString()
    {   return q + " at " + "(" + rx + ", " + ry + ")";  }
    ...
}
```

$$V_c(x, y) = k \frac{q}{r}$$

Key to OOP. An instance variable reference in a class method *refers to the value for the object that was used to invoke the method.*

Point charge implementation

text file named Charge.java →

```
public class Charge
{
    private double rx, ry; // position
    private double q;     // charge

    public Charge(double x0, double y0, double q0)
    {
        rx = x0;
        ry = y0;
        q = q0;
    }

    public double potentialAt(double x, double y)
    {
        double k = 8.99e09;
        double dx = x - rx;
        double dy = y - ry;
        return k * q / Math.sqrt(dx*dx + dy*dy);
    }

    public String toString()
    {
        return q + " at (" + rx + ", " + ry + ")";
    }
}

public static void main(String[] args)
{
    Charge c = new Charge(.72, .31, 20.1);
    System.out.println(c);
    StdOut.printf("%6.2e\n", c.potentialAt(.42, .71));
}
```

Point charge client: Potential visualization (helper methods)

Read point charges from StdIn.

- Uses Charge like any other type.
- Returns an array of Charges

Convert potential values to a color.

- Convert V to an 8-bit integer.
- Use grayscale.

```
public static Charge[] readCharges()
{
    int N = StdIn.readInt();
    Charge[] a = new Charge[N];
    for (int i = 0; i < N; k++)
    {
        double x0 = StdIn.readDouble();
        double y0 = StdIn.readDouble();
        double q0 = StdIn.readDouble();
        a[i] = new Charge(x0, y0, q0);
    }
    return a;
}
```

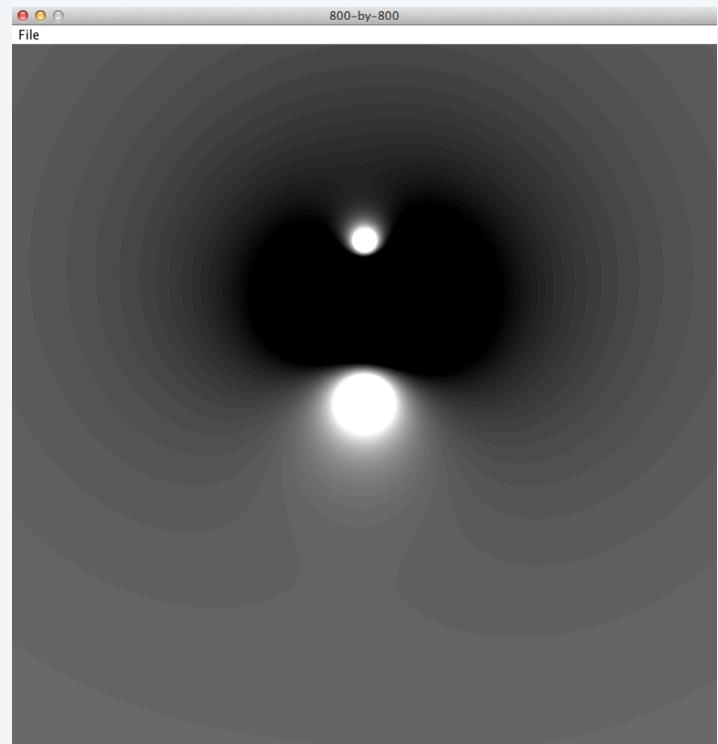

```
public static Color toColor(double V)
{
    V = 128 + V / 2.0e10;
    int t = 0;
    if (V > 255) t = 255;
    else if (V >= 0) t = (int) V;
    return new Color(t, t, t);
}
```

V											
t	0	1	...	37	38	39	...	128	...	254	255

Point charge client: Potential visualization

```
import java.awt.Color;
public class Potential
{
    public static Charge[] readCharges()
    { // See previous slide. }
    public static Color toColor()
    { // See previous slide. }
    public static void main(String[] args)
    {
        Charge[] a = readCharges();
        int SIZE = 800;
        Picture pic = new Picture(SIZE, SIZE);
        for (int col = 0; col < SIZE; col++)
            for (int row = 0; row < SIZE; row++)
            {
                double V = 0.0;
                for (int k = 0; k < a.length; k++)
                {
                    double x = 1.0 * col / SIZE;
                    double y = 1.0 * row / SIZE;
                    V += a[k].potentialAt(x, y);
                }
                pic.set(col, SIZE-1-row, toColor(V));
            }
        pic.show();
    }
}
```

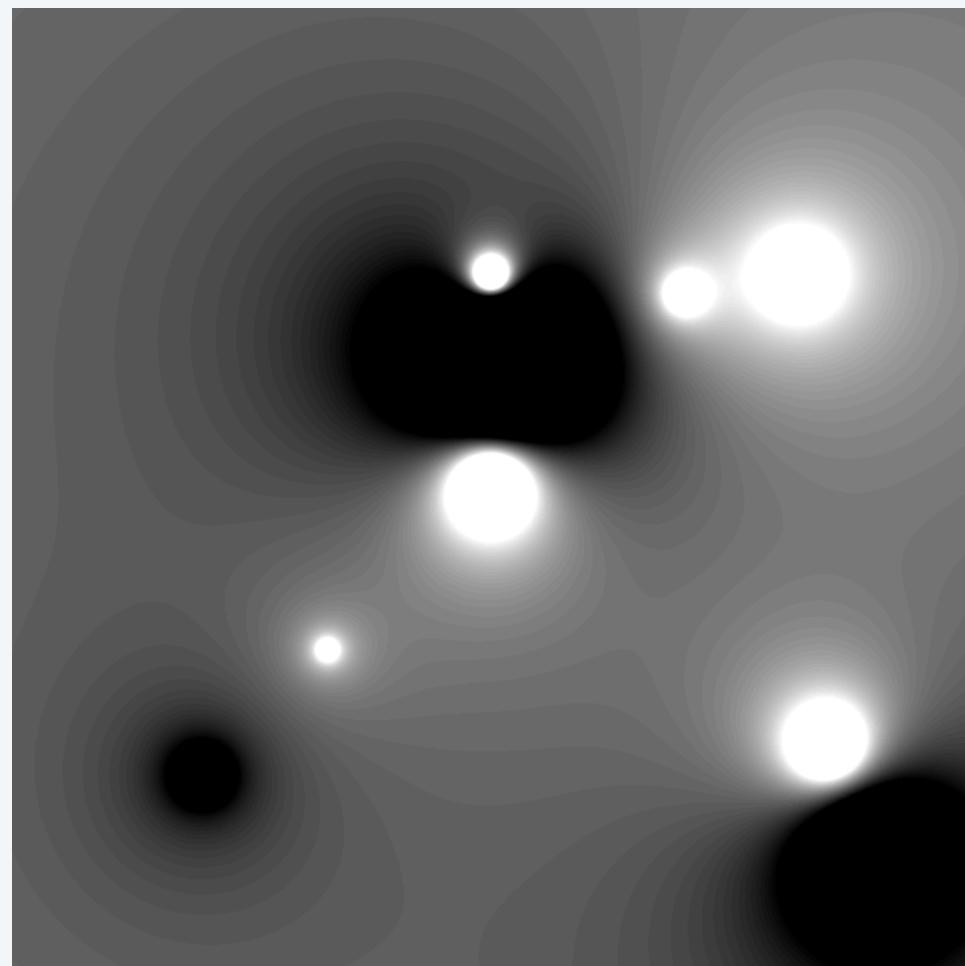

```

Potential visualization III: Discontinuous color map

```
public static Color toColor(double V)
{
    V = 128 + V / 2.0e10;
    int t = 0;
    if (V > 255) t = 255;
    else if (V >= 0) t = (int) V;
    t = t*37 % 255
    return new Color(t, t, t);
}
```

Potential visualization IV: Arbitrary discontinuous color map (a bug!)

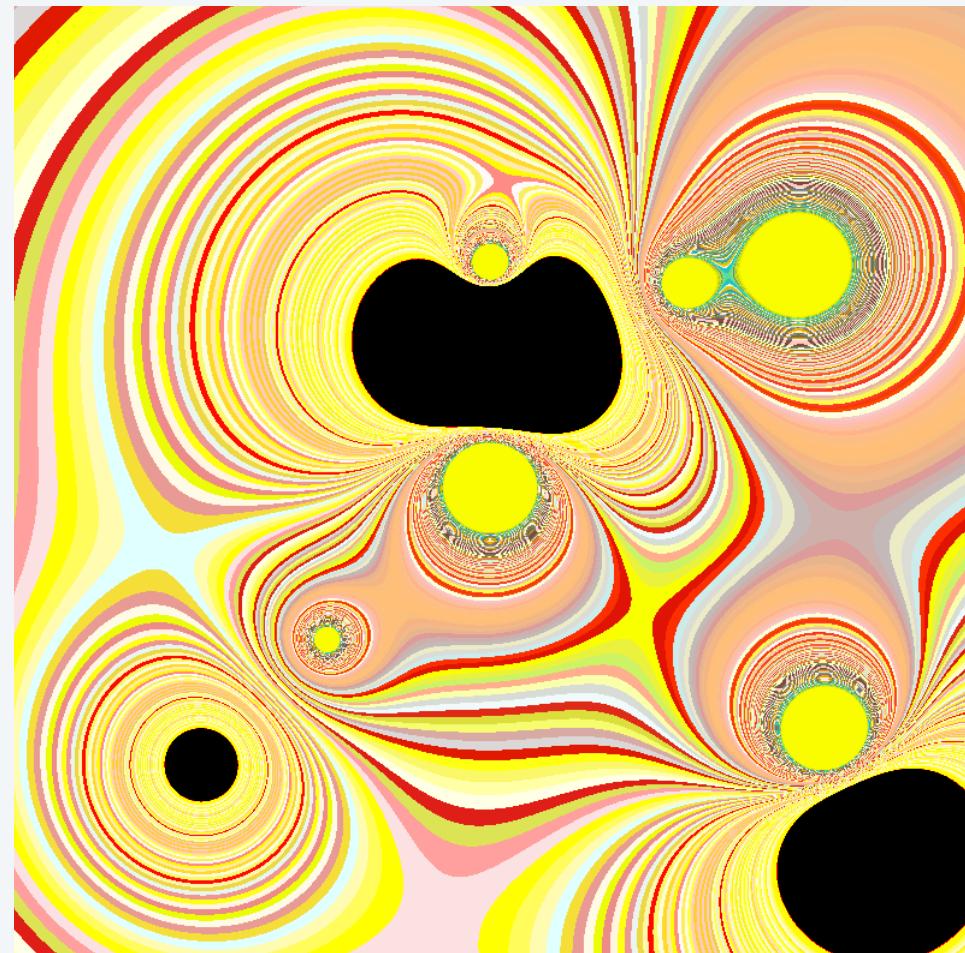

If you are an *artist*

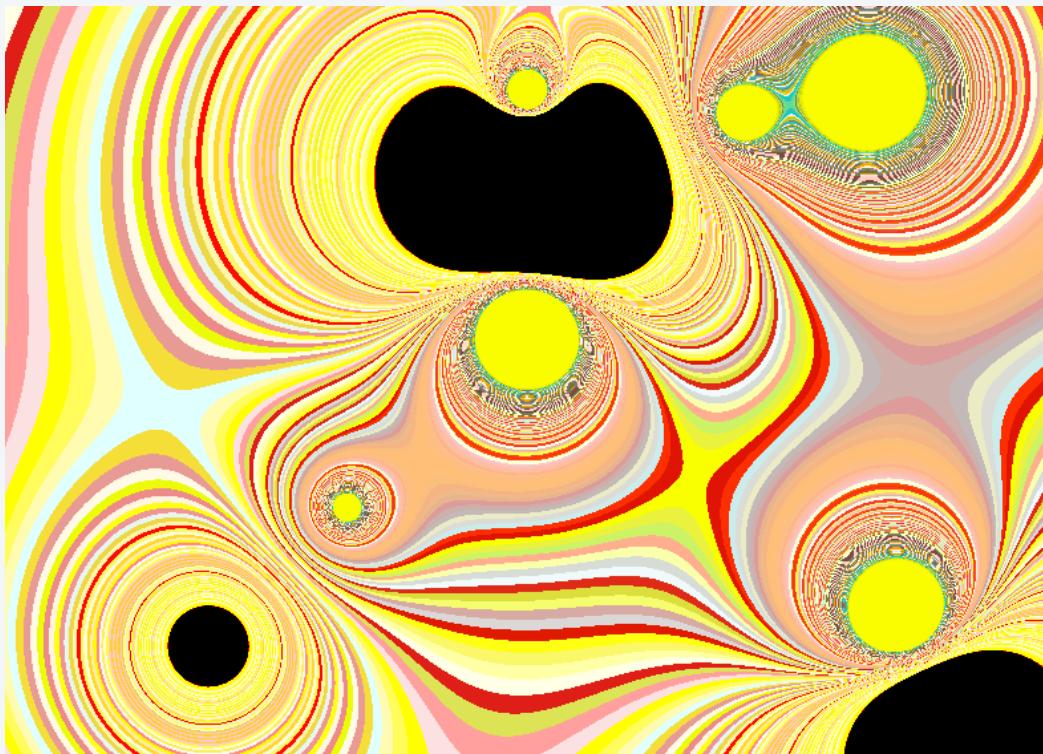

- Choose 255 beautiful colors.
- Put them in an array.
- Index with t to pick a color.

If you are an *computer scientist*

- Play with colors.
- Maybe you'll hit on something...

```
public static Color toColor(double V)
{
    V = 128 + V / 2.0e10;
    int t = 0;
    if (V > 255) t = 255;
    else if (V >= 0) t = (int) V;
    return Color.getHSBColor(t, t, t);
    return new Color(t, t, t);
}
```

TEQ 1 on OOP

Q. Fix the serious bug in this code:

```
public class Charge
{
    private double rx, ry;
    private double q;
    public Charge (double x0, double y0, double q0)
    {
        double rx = x0;
        double ry = y0;
        double q = q0;
    }
}
```

TEQ 1 on OOP

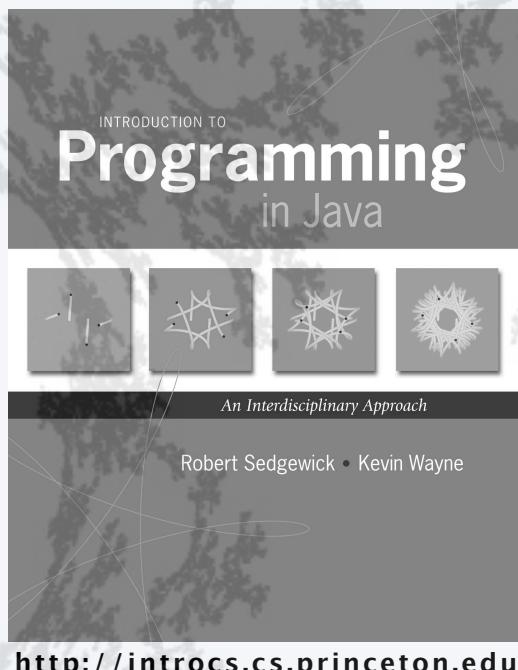

Q. Fix the serious bug in this code:

```
public class Charge
{
    private double rx, ry;
    private double q;
    public Charge (double x0, double y0, double q0)
    {
        double rx = x0;
        double ry = y0;
        double q = q0;
    }
}
```

A. Remove type declarations.
They create local variables,
giving *no way* for the method
to access the instance variables!

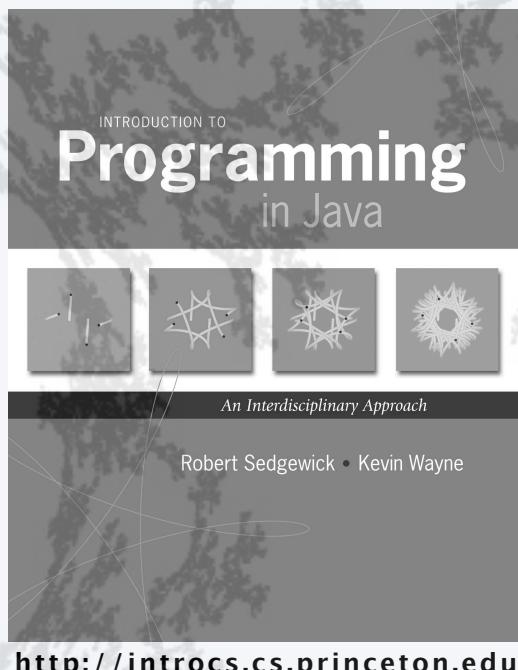

Object-oriented programmers pledge. "I will not shadow instance variables"

Every programmer makes this mistake,
and it is a difficult one to detect.

10. Creating Data Types

- Overview
- Point charges
- **Turtle graphics**
- Complex numbers

ADT for turtle graphics

A **turtle** is an idealized model of a plotting device.

An **ADT** allows us to write Java programs that manipulate turtles.

Seymour Papert
1928–

Values

position (x, y)	(.5, .5)	(.75, .75)	(.22, .12)
orientation	90°	135°	10°

The diagram shows four small blue turtle icons positioned at the corners of the grid. The top-left icon is oriented vertically upwards, the top-right is rotated 45 degrees counter-clockwise, the bottom-left is rotated 270 degrees counter-clockwise, and the bottom-right is rotated 10 degrees counter-clockwise.

API (operations)

public class Turtle

Turtle(double x0, double y0, double q0)

void turnLeft(double delta)

rotate delta degrees counterclockwise

void goForward(double step)

move distance step, drawing a line

Turtle graphics implementation: Test client

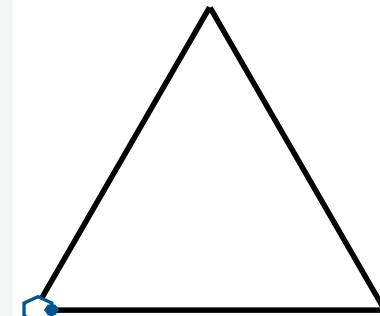

Best practice. Begin by implementing a simple test client.

```
public static void main(String[] args)
{
    Turtle turtle = new Turtle(0.0, 0.0, 0.0);
    turtle.goForward(1.0);
    turtle.turnLeft(120.0);
    turtle.goForward(1.0);
    turtle.turnLeft(120.0);
    turtle.goForward(1.0);
    turtle.turnLeft(120.0);
}
```

% java Turtle

Note: Client drew triangle
without computing $\sqrt{3}$

What we *expect*, once the implementation is done.

Turtle implementation: Instance variables and constructor

Instance variables define data-type values.

Constructors create and initialize new objects.

```
public class Turtle
{
    private double x, y;    ← instance variables
    private double angle;   ← are not final

    public Turtle(double x0, double y0, double a0)
    {
        x = x0;
        y = y0;
        angle = a0;
    }
    ...
}
```

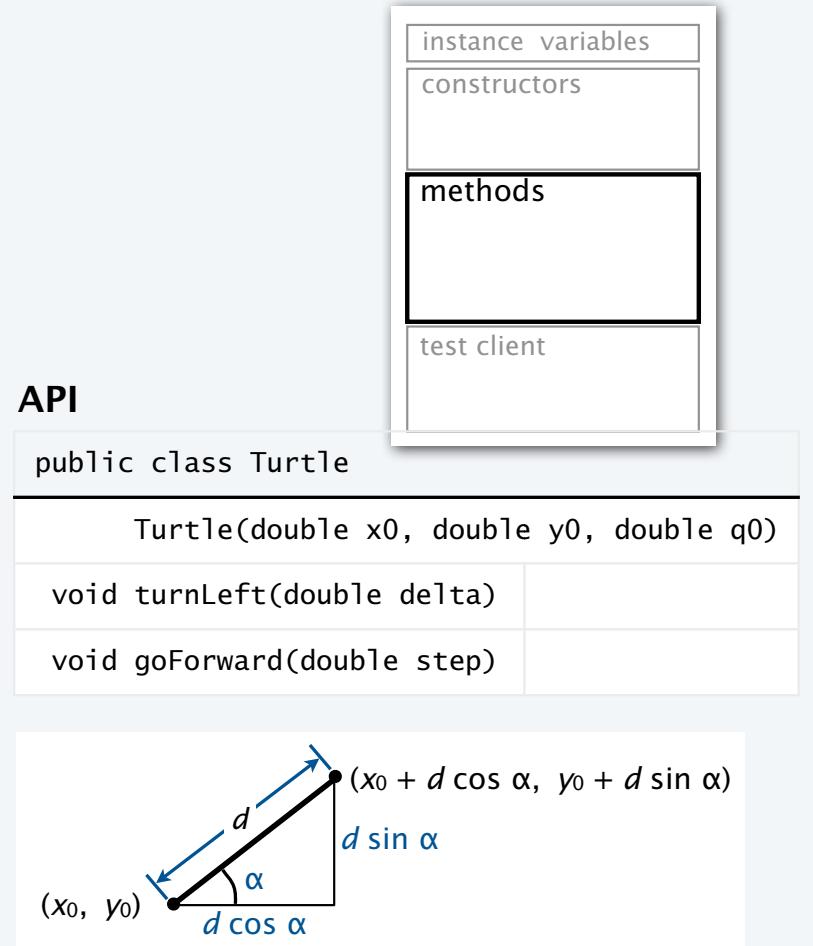

Values	position (x, y)	(.5, .5)	(.75, .75)	(.22, .12)
	orientation	90°	135°	10°
		↙	↗	↘
				↙

Turtle implementation: Methods

Methods define data-type operations (implement APIs).

```
public class Turtle
{
    ...
    public void turnLeft(double delta)
    { angle += delta; }
    public void goForward(double d)
    {
        double oldx = x;
        double oldy = y;
        x += d * Math.cos(Math.toRadians(angle));
        y += d * Math.sin(Math.toRadians(angle));
        StdDraw.line(oldx, oldy, x, y);
    }
    ...
}
```

- Complex numbers

10. Creating Data Types

- Overview
- Point charges
- Turtle graphics
- Complex numbers

Crash course in complex numbers

A **complex number** is a number of the form $a + bi$ where a and b are real and $i \equiv \sqrt{-1}$.

Complex numbers are a *quintessential mathematical abstraction* that have been used for centuries to give insight into real-world problems not easily addressed otherwise.

To perform **algebraic operations** on complex numbers, use real algebra, replace i^2 by -1 and collect terms.

- Addition example: $(3 + 4i) + (-2 + 3i) = 1 + 7i$.
- Multiplication example: $(3 + 4i) + (-2 + 3i) = -18 + i$.

Leonhard Euler
1707–1783

A. L. Cauchy
1789–1857

The **magnitude** or **absolute value** of a complex number $a + bi$ is $|a + bi| = \sqrt{a^2 + b^2}$.

Example: $|3 + 4i| = 5$

Applications: Signal processing, control theory, quantum mechanics, analysis of algorithms...

ADT for complex numbers

A **complex number** is a number of the form $a + bi$ where a and b are real and $i \equiv \sqrt{-1}$.

An **ADT** allows us to write Java programs that manipulate complex numbers.

Values	<i>complex number</i>	$3 + 4i$	$-2 + 2i$
	real part	3.0	-2.0
	imaginary part	4.0	2.0

API (operations)

public class Complex	
	Complex(double real, double imag)
Complex plus(Complex b)	<i>sum of this number and b</i>
Complex times(Complex b)	<i>product of this number and b</i>
double abs()	<i>magnitude</i>
String toString()	<i>string representation</i>

Complex number data type implementation: Test client

Best practice. Begin by implementing a simple test client.

```
public static void main(String[] args)
{
    Complex a = new Complex( 3.0, 4.0);
    Complex b = new Complex(-2.0, 3.0);
    StdOut.println("a = " + a);
    StdOut.println("b = " + b);
    StdOut.println("a * b = " + a.times(b));
}
```

$$a = v + wi$$

$$b = x + yi$$

$$\begin{aligned} a \times b &= vx + vyi + wxi + wyi^2 \\ &= vx - wy + (vy + wx)i \end{aligned}$$

```
% java Complex
a = 3.0 + 4.0i
b = -2.0 + 3.0i
a * b = -18.0 + 1.0i
```

What we *expect*, once the implementation is done.

Complex number data type implementation: Instance variables and constructor

Instance variables define data-type values.

Constructors create and initialize new objects.

```
public class Complex
{
    private final double re; ← instance variables
    private final double im; ← are final

    public Complex(double real, double imag)
    {
        re = real;
        im = imag;
    }
    ...
}
```

Values

<i>complex number</i>	$3 + 4i$	$-2 + 2i$
real part	3.0	-2.0
imaginary part	4.0	2.0

Complex number data type implementation: Methods

Methods define data-type operations (implement APIs).

```
public class Complex
{
    ...
    public Complex plus(Complex b)
    {
        double real = re + b.re;
        double imag = im + b.im;
        return new Complex(real, imag);
    }
    public Complex times(Complex b)
    {
        double real = a.re * b.re - a.im * b.im;
        double imag = a.re * b.im + a.im * b.re;
        return new Complex(real, imag);
    }
    public double abs()
    {
        return Math.sqrt(re*re + im*im);
    }
    public String toString()
    {
        return re + " + " + im + "i";
    }
    ...
}
```

The Mandelbrot set

The *Mandelbrot set* is a set of complex numbers.

- Represent each complex number $x + yi$ by a point (x, y) in the plane.
- If a point is *in* the set, we color it BLACK.
- If a point is *not* in the set, we color it WHITE.

Examples

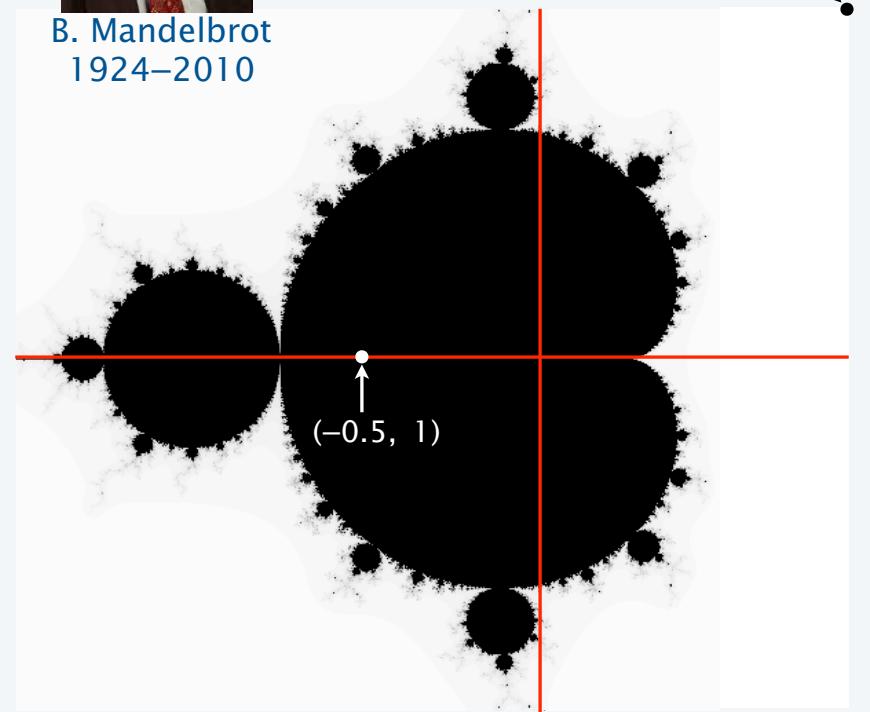

- *In* the set: $-0.5 + 0i$.
- *Not in* the set: $1 + i$.

Challenge

- No simple formula exists for testing whether a number is in the set.
- Instead, the set is defined by an *algorithm*.

B. Mandelbrot
1924–2010

Determining whether a point is in the Mandelbrot set

Is a complex number z_0 in the set?

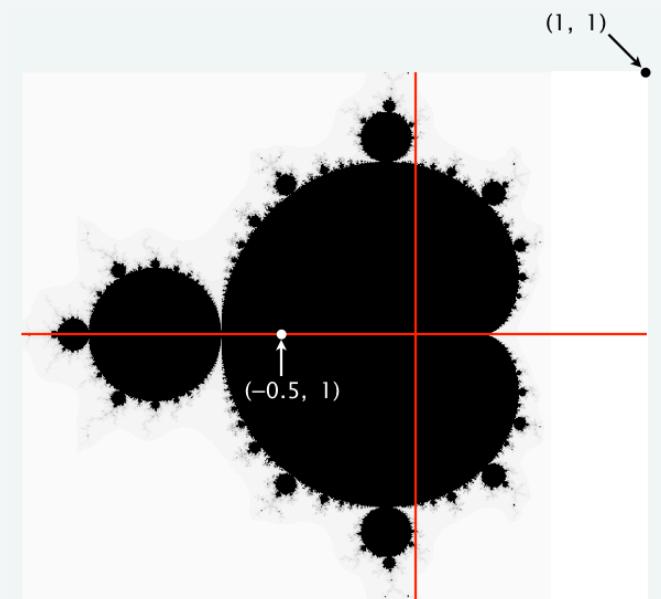

- Iterate $z_{t+1} = (z_t)^2 + z_0$.
- If $|z_t|$ diverges to infinity, z_0 is *in* the set.
- If not, z_0 is *not* in the set.

t	z_t
0	$-1/2 + 0i$
1	$-1/4 + 0i$
2	$-7/16 + 0i$
3	$-79/256 + 0i$
4	$-26527/65536 + 0i$

↑
converges to 0
 $z = -1/2 + 0i$ is *in* the set

t	z_t
0	$1 + i$
1	$1 + 3i$
2	$-7 + 7i$
3	$1 - 97i$
4	$-9407 - 193i$

↑
diverges to infinity
 $z = 1 + i$ is *not* in the set

$$(1+i)^2 + (1+i) = 1 + 2i + i^2 + 1 + i = 1+3i$$

$$(1+3i)^2 + (1+i) = 1 + 6i + 9i^2 + 1 + i = -7+7i$$

Plotting the Mandelbrot set

Practical issues

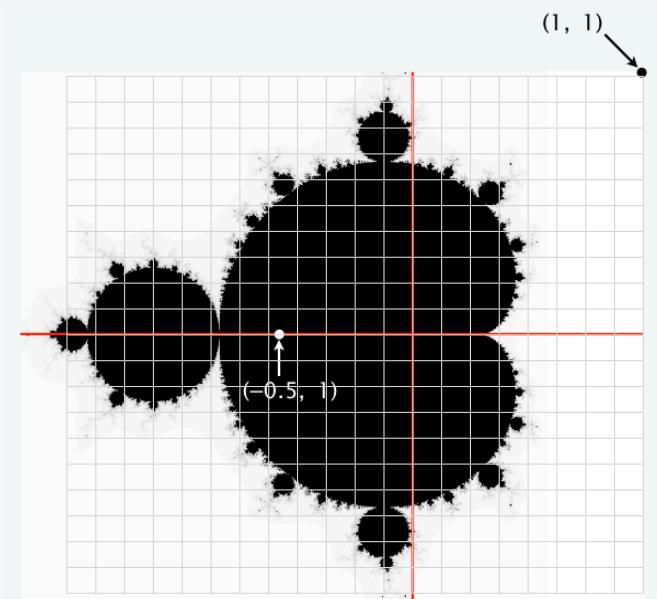

- Cannot plot infinitely many points.
- Cannot iterate infinitely many times.

Approximate solution for first issue

- Sample from an N -by- N grid of points in the plane.
- Zoom in to see more detail (stay tuned!).

Approximate solution for second issue

- Fact: if $|z_t| > 2$ for any t , then z is *not* in the set.
- Pseudo-fact: if $|z_{255}| \leq 2$ then z is "likely" in the set.

Important note: Solutions imply significant computation.

Complex number client: Mandelbrot set visualization (helper method)

Mandlebrot function of a complex number.

- Returns WHITE if the number is not in the set.
- Returns BLACK if the number is (probably) in the set.

```
public static Color mand(Complex z0)
{
    Complex z = z0;
    for (int t = 0; t < 255; t++)
    {
        if (z.abs() > 2.0) return Color.WHITE; ←
        z = z.times(z);
        z = z.plus(z0);
    }
    return Color.BLACK;
}
```

For a more dramatic picture,
return new Color(255-t, 255-t, 255-t)
or colors picked from a color table.

Complex number client: Mandelbrot set visualization

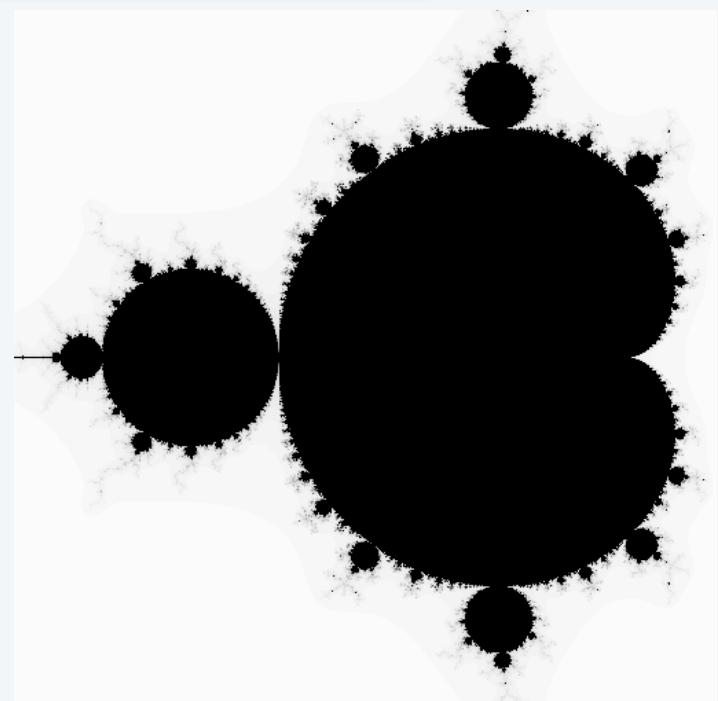

```
import java.awt.Color;
public class Mandelbrot
{
    public static Color mand(Complex z0)
    { // See previous slide. }
    public static void main(String[] args)
    {
        double xc    = Double.parseDouble(args[0]);
        double yc    = Double.parseDouble(args[1]);
        double size = Double.parseDouble(args[2]);
        int N = 512;
        Picture pic = new Picture(N, N);

        for (int col = 0; col < N; col++)
            for (int row = 0; row < N; row++)  
                {  
                    double x0 = xc - size/2 + size*col/N;  
                    double y0 = yc - size/2 + size*row/N;  
                    Complex z0 = new Complex(x0, y0);  
                    Color color = mand(z0);  
                    pic.set(col, N-1-row, color);  
                }  
        pic.show();  
    }
}
```

10. Creating Data Types

- Overview
- Point charges
- Turtle graphics
- Complex numbers

OOP summary

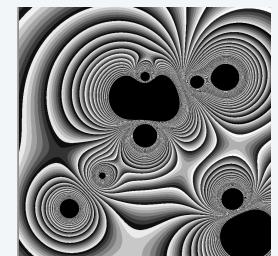

Object-oriented programming (OOP).

- Create your own data types (sets of values and ops on them).
- Use them in your programs (manipulate *objects*).

OOP helps us simulate the physical world

- Java objects model real-world objects.
- Not always easy to make model reflect reality.
- Examples: charged particle, color, sound, genome....

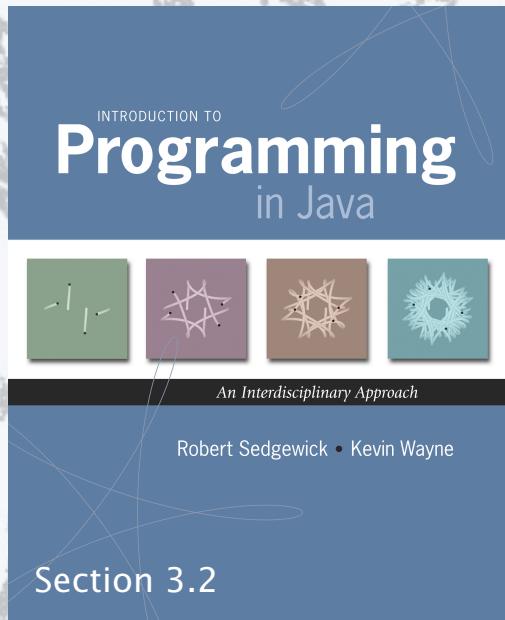

OOP helps us extend the Java language

- Java doesn't have a data type for every possible application.
- Data types enable us to add our own abstractions.
- Examples: complex, vector, polynomial, matrix, picture....
