Princeton University

Computer Science 217: Introduction to Programming Systems

The C Programming Language

Part 2

Agenda

Data Types

Operators

Statements

I/O Facilities

Operators

Computers represent integers as bits

Arithmetic operations: +, -, *, /, etc.

Bit operations: and, or, xor, shift, etc.

Typical language design (1970s): provide *abstraction* so that one does not confuse integers with their representation

The C language design: no abstraction,

revel in the "pun" between integers and their representation

Operators

Decisions

- Provide typical arithmetic operators: + * / %
- Provide typical relational operators: == != < <= > >=
 - Each evaluates to 0 ⇒ FALSE or 1 ⇒ TRUE
- Provide typical logical operators: ! && | |
 - Each interprets 0 ⇒ FALSE, ≠0 ⇒ TRUE
 - Each evaluates to 0 ⇒ FALSE or 1 ⇒TRUE
- Provide bitwise operators: ~ & | ^ >> <<
- Provide a cast operator: (type)

Aside: Logical vs. Bitwise Ops

Logical NOT (!) vs. bitwise NOT (~)

• ! 1 (TRUE) \Rightarrow 0 (FALSE)

```
Decimal Binary

1 00000000 00000000 00000000 00000001
! 1 00000000 00000000 00000000 00000000
```

• ~ 1 (TRUE) \Rightarrow -2 (TRUE)

```
Decimal Binary
1 00000000 00000000 00000000 00000001
~ 1 1111111 11111111 11111111 11111110
```

Implication:

- Use logical NOT to control flow of logic
- Use bitwise NOT only when doing bit-level manipulation

Aside: Logical vs. Bitwise Ops

Logical AND (&&) vs. bitwise AND (&)

• 2 (TRUE) && 1 (TRUE) \Rightarrow 1 (TRUE)

• 2 (TRUE) & 1 (TRUE) \Rightarrow 0 (FALSE)

Aside: Logical vs. Bitwise Ops

Implication:

- Use logical AND to control flow of logic
- Use bitwise AND only when doing bit-level manipulation

Same for logical OR (||) and bitwise OR (|)

Assignment Operator

Typical programming language of 1970s:

Statements, Expressions

```
stmt ::=
  a:=exp
  if exp then stmt else stmt
| while exp do stmt
 | begin stmtlist end
stmtlist ::= stmt | stmtlist ; stmt
exp ::=
 id | exp+exp | exp-exp | -exp
  | (exp) | ...
```

C language: assignment is an *expression!*

```
stmt ::=
  exp;
{ stmtlist }
if (exp) stmt else stmt
while (exp) stmt
stmtlist ::= stmt | stmtlist stmt
exp ::=
 id | exp+exp | exp-exp | -exp
| id=exp | exp,exp | exp?exp:exp
(exp) | ...
```

Assignment Operator

Decisions

- Provide assignment operator: =
 - Side effect: changes the value of a variable
 - Evaluates to the new value of the variable

Assignment Operator Examples

Examples

```
i = 0;
   /* Side effect: assign 0 to i.
      Evaluate to 0.
j = i = 0; /* Assignment op has R to L associativity */
   /* Side effect: assign 0 to i.
      Evaluate to 0.
      Side effect: assign 0 to j.
      Evaluate to 0. */
while ((i = getchar()) != EOF) ...
   /* Read a character.
      Side effect: assign that character to i.
      Evaluate to that character.
      Compare that character to EOF.
      Evaluate to 0 (FALSE) or 1 (TRUE). */
```

Special-Purpose Assignment Operators

Decisions

Provide special-purpose assignment operators:

```
+= -= *= /= ~= &= |= ^= <<= >>=
```

Examples

```
i += j same as i = i + j

i /= j same as i = i / j

i |= j same as i = i | j

i >>= j same as i = i >> j
```

Special-Purpose Assignment Operators

Design decision

• Is it worth mucking up the language definition with this feature? Does it really make programs any faster, or easier to read?

Answer:

Not much. But consider this example:

```
p->data[i+j*10].first->next += 1;
```

Special-Purpose Assignment Operators

Increment and decrement operators: ++ --

Prefix and postfix forms

Examples

```
(1) i = 5;
    j = ++i;
(2) i = 5;
    j = i++;
    What is the
    value of i? Of j?

(3) i = 5;
    j = ++i + ++i;

(4) i = 5;
    j = i++ + i++;
```

Memory allocation

Typical programming language of 1970s:

Special program statement to allocate a new object

stmt ::=

new p

This is not so different from Java's p=new(MyClass)

Difficulties:

- 1.system standard allocator could be slow, or inflexible
- 2. What about deallocation?
 - Explicit "free" leads to bugs
 - Automatic garbage collection too expensive?

C language

Nothing built-in

- malloc, free functions provided in standard library
- •allow programmers to roll their own allocation systems

Difficulties:

- 1.System standard allocator could be slow, or inflexible (but that's mitigated by roll-your-own)
- Explicit "free" leads to bugs
 Turns out, by now we know, automatic garbage collection isn't too expensive after all!

Sizeof Operator

Malloc function needs to be told how many bytes to allocate

```
struct foo {int a, b; float c;} *p;
p = malloc(12); /* this is correct but not portable */
```

Issue: How can programmers determine data sizes?

Rationale:

- The sizes of most primitive types are unspecified
- Sometimes programmer must know sizes of primitive types
 - E.g. when allocating memory dynamically
- Hard code data sizes ⇒ program not portable
- C must provide a way to determine the size of a given data type programmatically

Sizeof Operator

Decisions

- Provide a **sizeof** operator
 - Applied at compile-time
 - Operand can be a data type
 - Operand can be an expression
 - Compiler infers a data type

Examples, on CourseLab

- sizeof(int) $\Rightarrow 4$
- When i is a variable of type int...
- sizeof(i) $\Rightarrow 4$
- sizeof(i+1)
- sizeof(i++ * ++i 5)

What is the value?

Other Operators

Issue: What other operators should C have?

Decisions

- Function call operator
 - Should mimic the familiar mathematical notation
 - function(arg1, arg2, ...)
- Conditional operator: ?:
 - The only ternary operator
 - See King book
- Sequence operator: ,
 - See King book
- Pointer-related operators: & *
 - Described later in the course
- Structure-related operators: . ->
 - Described later in the course

Operators Summary: C vs. Java

Java only

>>> right shift with zero fill

• new create an object

• instanceof is left operand an object of class right operand?

p.f object field select

C only

p.f structure field select

* dereference

• p->f dereference then structure member select: (*p).f

address of

• , sequence

• sizeof compile-time size of

Operators Summary: C vs. Java

Related to type boolean:

- Java: Relational and logical operators evaluate to type boolean
- C: Relational and logical operators evaluate to type int
- Java: Logical operators take operands of type boolean
- C: Logical operators take operands of any primitive type or memory address

Agenda

Data Types

Operators

Statements

I/O Facilities

Sequence Statement

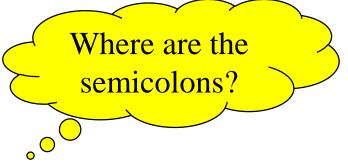

Issue: How should C implement sequence?

Decision

Compound statement, alias block

```
{
    statement1
    statement2
    ...
}
```

Selection Statements

Issue: How should C implement selection?

Decisions

• if statement, for one-path, two-path decisions

```
if (expr)
    statement1
```

```
if (expr)
    statement1
else
    statement2
```

0 ⇒ FALSE non-0 ⇒ TRUE

Selection Statements

Decisions (cont.)

• switch and break statements, for multi-path decisions on a single integerExpr

What happens if you forget break?

Repetition Statements

Issue: How should C implement repetition?

Decisions

while statement; test at leading edge

```
while (expr)
statement
```

• for statement; test at leading edge, increment at trailing edge

```
for (initialExpr; testExpr; incrementExpr)
    statement
```

do...while statement; test at trailing edge

```
do
    statement
while (expr);
```

```
0 ⇒ FALSE
non-0 ⇒ TRUE
```

Declaring Variables

Issue: Should C require variable declarations?

Rationale:

- Declaring variables allows compiler to check spelling (compile-time error messages are easier for programmer than debugging strange behavior at run time!)
- Declaring variables allows compiler to allocate memory more efficiently

Where are variables declared?

Typical 1960s language: Cla

Global variables

Typical 1970s language:

- Global variables
- Local variables declared just before function body

C language:

- Global variables
- Local variables can be declared at beginning of any {block}, e.g.,

```
{int i=6, j;
  j=7;
  if (i>j)
        {int x; x=i+j; return x;}
  else {int y; y=i-j; return y;}
} scope of variable y ends
  at matching close brace
```

Repetition Statements

Decisions (cont.)

Cannot declare loop control variable in for statement

```
{
    ...
    for (int i = 0; i < 10; i++)
        /* Do something */
    ...
}</pre>
```

Illegal in C (nobody thought of that idea in 1970s)

```
{
  int i;
  ...
  for (i = 0; i < 10; i++)
      /* Do something */
  ...
}</pre>
```

Legal in C

Declaring Variables

Decisions (cont.):

 Declaration statements must appear before any other kind of statement in compound statement

```
int i;
/* Non-declaration
    stmts that use i. */
i = i+1;
int j;
/* Non-declaration
    stmts that use j. */
j = j+1;
}
```

Illegal in C (nobody thought of that idea in 1970s)

```
int i;
int j;
...
/* Non-declaration
    stmts that use i. */
i = i+1;
/* Non-declaration
    stmts that use j. */
j = j+1;
}
```

Legal in C

Other Control Statements

Issue: What other control statements should C provide?

Decisions

- break statement (revisited)
 - Breaks out of closest enclosing switch or repetition statement
- continue statement
 - Skips remainder of current loop iteration
 - Continues with next loop iteration
 - When used within for, still executes incrementExpr
- goto statement
 - Jump to specified label

Declaring Variables

Decisions:

- Require variable declarations
- Provide declaration statement
- Programmer specifies type of variable (and other attributes too)

Examples

```
• int i;
• int i, j;
• int i = 5;
• const int i = 5; /* value of i cannot change */
• static int i; /* covered later in course */
• extern int i; /* covered later in course */
```

Computing with Expressions

Issue: How should C implement computing with expressions?

Decisions:

Provide expression statement
 expression ;

Computing with Expressions

Examples

```
i = 5;
   /* Side effect: assign 5 to i.
      Evaluate to 5. Discard the 5. */
j = i + 1;
  /* Side effect: assign 6 to j.
      Evaluate to 6. Discard the 6. */
printf("hello");
   /* Side effect: print hello.
      Evaluate to 5. Discard the 5. */
i + 1;
   /* Evaluate to 6. Discard the 6. */
5;
   /* Evaluate to 5. Discard the 5. */
```

Declaration statement:

- Java: Compile-time error to use a local variable before specifying its value
- C: Run-time error to use a local variable before specifying its value

final and const

- Java: Has final variables
- C: Has const variables

Expression statement

- Java: Only expressions that have a side effect can be made into expression statements
- **C**: Any expression can be made into an expression statement

Compound statement:

- Java: Declarations statements can be placed anywhere within compound statement
- C: Declaration statements must appear before any other type of statement within compound statement

if statement

- Java: Controlling expr must be of type boolean
- C: Controlling expr can be any primitive type or a memory address (0 ⇒ FALSE, non-0 ⇒ TRUE)

while statement

- Java: Controlling expr must be of type boolean
- C: Controlling expr can be any primitive type or a memory address (0 ⇒ FALSE, non-0 ⇒ TRUE)

do...while statement

- Java: Controlling expr must be of type boolean
- C: Controlling expr can be of any primitive type or a memory address (0 ⇒ FALSE, non-0 ⇒ TRUE)

for statement

- Java: Controlling expr must be of type boolean
- C: Controlling expr can be of any primitive type or a memory address (0 ⇒ FALSE, non-0 ⇒ TRUE)

Loop control variable

- Java: Can declare loop control variable in initexpr
- C: Cannot declare loop control variable in initexpr

break statement

- Java: Also has "labeled break" statement
- C: Does not have "labeled break" statement

continue statement

- Java: Also has "labeled continue" statement
- C: Does not have "labeled continue" statement

goto statement

- Java: Not provided
- **C**: Provided (but don't use it!)

Agenda

Data Types

Operators

Statements

I/O Facilities

I/O Facilities

Issue: Should C provide I/O facilities?

(many languages of the 1960s / 1970s had built-in specialpurpose commands for input/output)

- Unix provides the file abstraction
 - A file is a sequence of characters with an indication of the current position
- Unix provides 3 standard files
 - Standard input, standard output, standard error
- C should be able to use those files, and others
- I/O facilities are complex
- C should be small/simple

I/O Facilities

- Do not provide I/O facilities in the language
- Instead provide I/O facilities in standard library
 - Constant: EOF
 - Data type: FILE (described later in course)
 - Variables: stdin, stdout, and stderr
 - Functions: ...

Reading Characters

Issue: What functions should C provide for reading characters?

- Need function to read a single character from stdin
 - ... And indicate failure

Reading Characters

Decisions

- Provide getchar() function*
- Define getchar() to return EOF upon failure
 - EOF is a special non-character int
- Make return type of getchar () wider than char
 - Make it int; that's the natural word size

Reminder

There is no such thing as "the EOF character"

*actually, a macro...

Writing Characters

Issue: What functions should C provide for writing characters?

Thought process

Need function to write a single character to stdout

- Provide putchar () function
- Define putchar () to have int parameter
 - For symmetry with getchar()

Reading Other Data Types

Issue: What functions should C provide for reading data of other primitive types?

- Must convert external form (sequence of character codes) to internal form
- Could provide getshort(), getint(), getfloat(), etc.
- Could provide parameterized function to read any primitive type of data

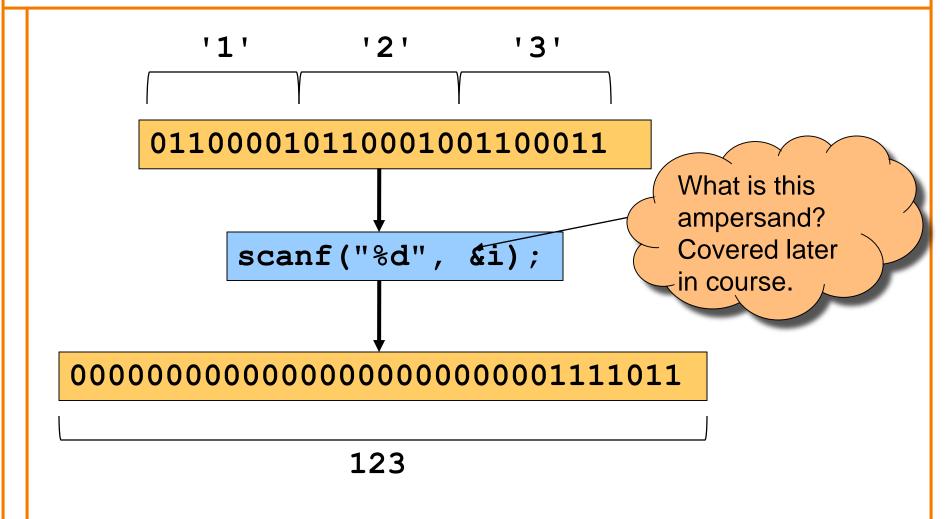

Reading Other Data Types

- Provide scanf() function
 - Can read any primitive type of data
 - First parameter is a format string containing conversion specifications

Reading Other Data Types

See King book for conversion specifications

Writing Other Data Types

Issue: What functions should C provide for writing data of other primitive types?

- Must convert internal form to external form (sequence of character codes)
- Could provide putshort(), putint(), putfloat(), etc.
- Could provide parameterized function to write any primitive type of data

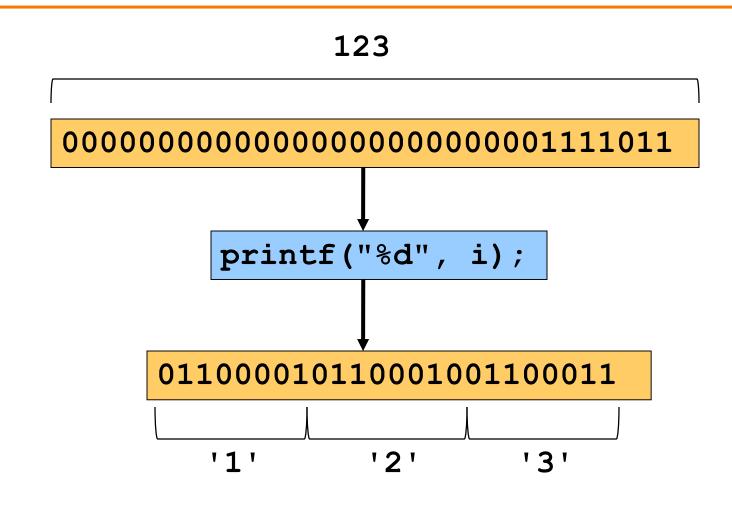

Writing Other Data Types

- Provide printf() function
 - Can write any primitive type of data
 - First parameter is a format string containing conversion specifications

Writing Other Data Types

See King book for conversion specifications

Other I/O Facilities

Issue: What other I/O functions should C provide?

Decisions

- fopen(): Open a stream
- fclose(): Close a stream
- fgetc(): Read a character from specified stream
- fputc(): Write a character to specified stream
- gets (): Read a line from stdin. Brain-damaged, never use this!
- fgets (): Read a line/string from specified stream
- fputs (): Write a line/string to specified stream
- fscanf(): Read data from specified stream
- fprintf(): Write data to specified stream

Described in King book, and later in the course after covering files, arrays, and strings

Summary

C design decisions and the goals that affected them

- Data types
- Operators
- Statements
- I/O facilities

Knowing the design goals and how they affected the design decisions can yield a rich understanding of C

Cast operator has multiple meanings:

- (1) Cast between integer type and floating point type:
 - Compiler generates code
 - At run-time, code performs conversion

```
i = (int)f
```

(2) Cast between floating point types of different sizes:

- Compiler generates code
- At run-time, code performs conversion

-27.375

```
d = (double) f
```

-27.375

(3) Cast between integer types of different sizes:

- Compiler generates code
- At run-time, code performs conversion

- (4) Cast between integer types of same size:
 - Compiler generates no code
 - Compiler views given bit-pattern in a different way

```
i 111111111111111111111111 -2
u = (unsigned int)i
u 1111111111111111111111 4294967294
```
