"More computing sins are committed in the name of efficiency (without necessarily achieving it) than for any other single reason—including blind stupidity. " – William A. Wulf

Summary of the performance of symbol-table implementations

Order of growth of the frequency of operations.

implementation		typical case	ordered	operations	
	search	insert	delete	operations	on keys
red-black BST	log n	log n	log n	•	compareTo()
hash table	1 †	1 †	1 †		equals() hashCode()

† under uniform hashing assumption

- Q. Can we do better?
- A. Yes, if we can avoid examining the entire key, as with string sorting.

String symbol table. Symbol table specialized to string keys.

public class	<pre>StringST<value></value></pre>	
	<pre>StringST()</pre>	create an empty symbol table
void	put(<mark>String</mark> key, Value val)	put key–value pair into the symbol table
Value	get(<mark>String</mark> key)	return value paired with given key
void	delete(String key)	delete key and corresponding value
	•	•

Goal. Faster than hashing, more flexible than BSTs.

	character accesses (typical case)				dedup	
implementation	search hit	search miss	insert	space (references)	moby.txt	actors.txt
red-black BST	$L + c \lg^2 n$	$c \lg^2 n$	$c \lg^2 n$	4 n	1.4	97.4
hashing (linear probing)	L	L	L	4 n to 16 n	0.76	40.6

 Parameters n = number of strings L = length of string R = radix 	file	size	words	distinct
	moby.txt	1.2 MB	210 K	32 K
	actors.txt	82 MB	11.4 M	900 K

Challenge. Efficient performance for string keys.

5.2 TRIES

R-way tries

ternary search tries

character-based operations

Algorithms

ROBERT SEDGEWICK | KEVIN WAYNE

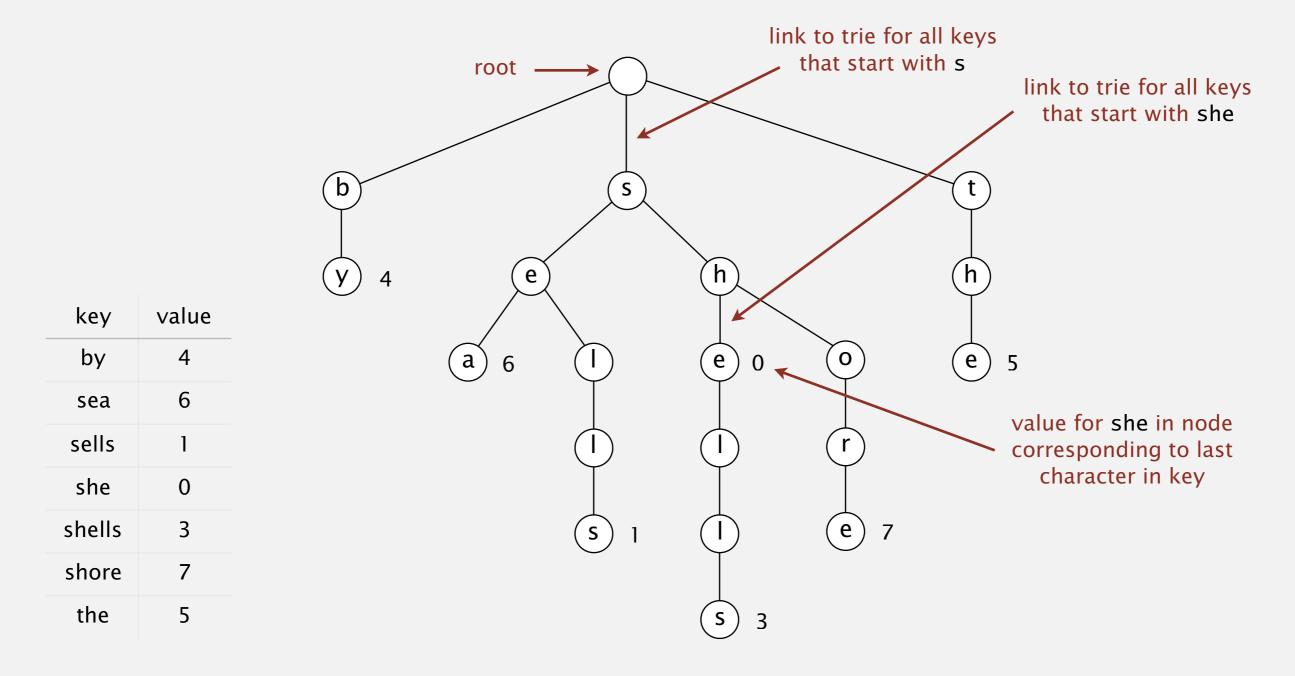

http://algs4.cs.princeton.edu

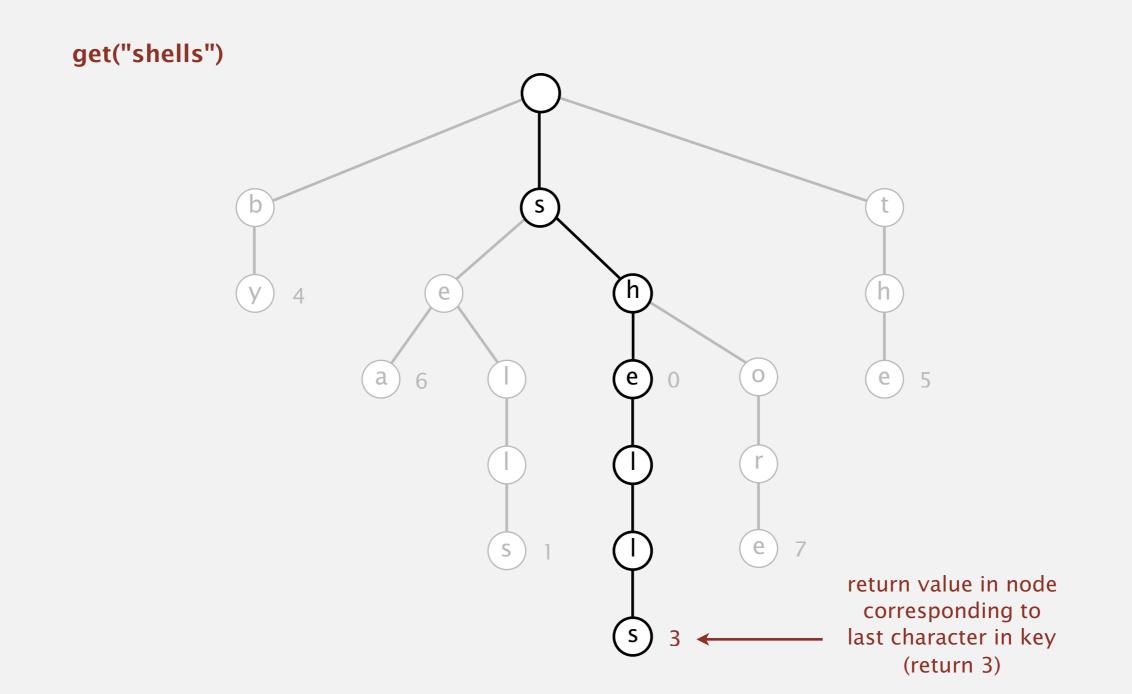

Tries

Tries. [from retrieval, but pronounced "try"]

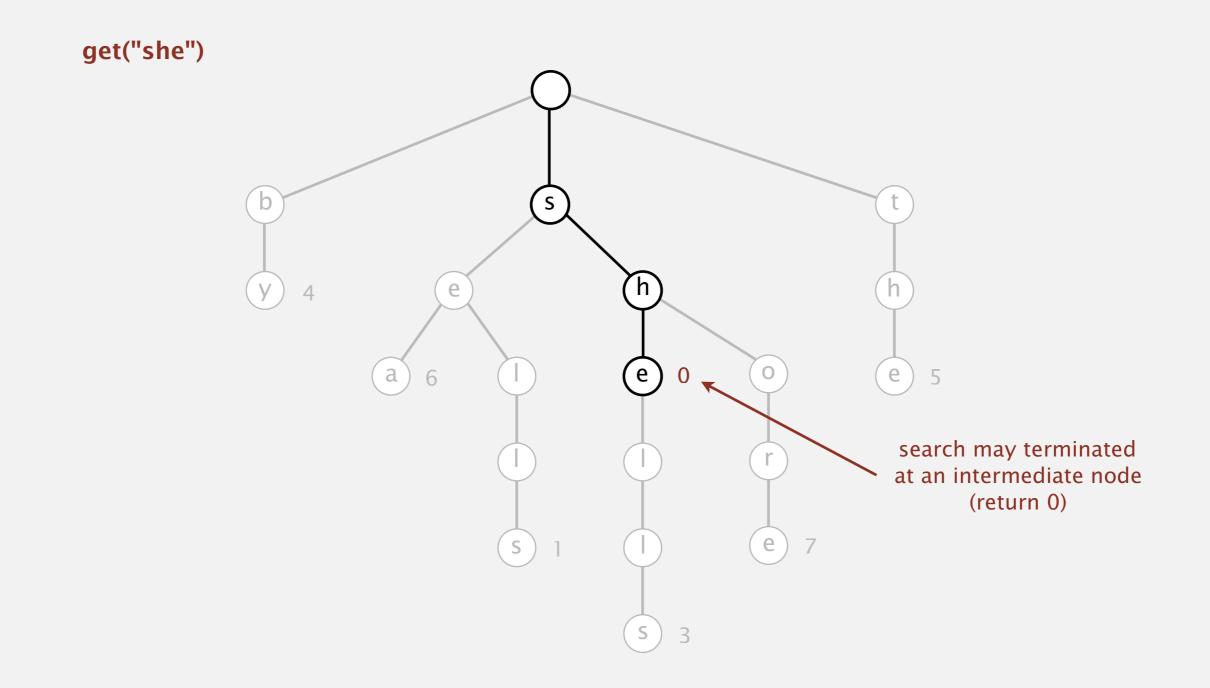

- Store characters in nodes (not keys).
- Each node has *R* children, one for each possible character. (for now, we do not draw null links)

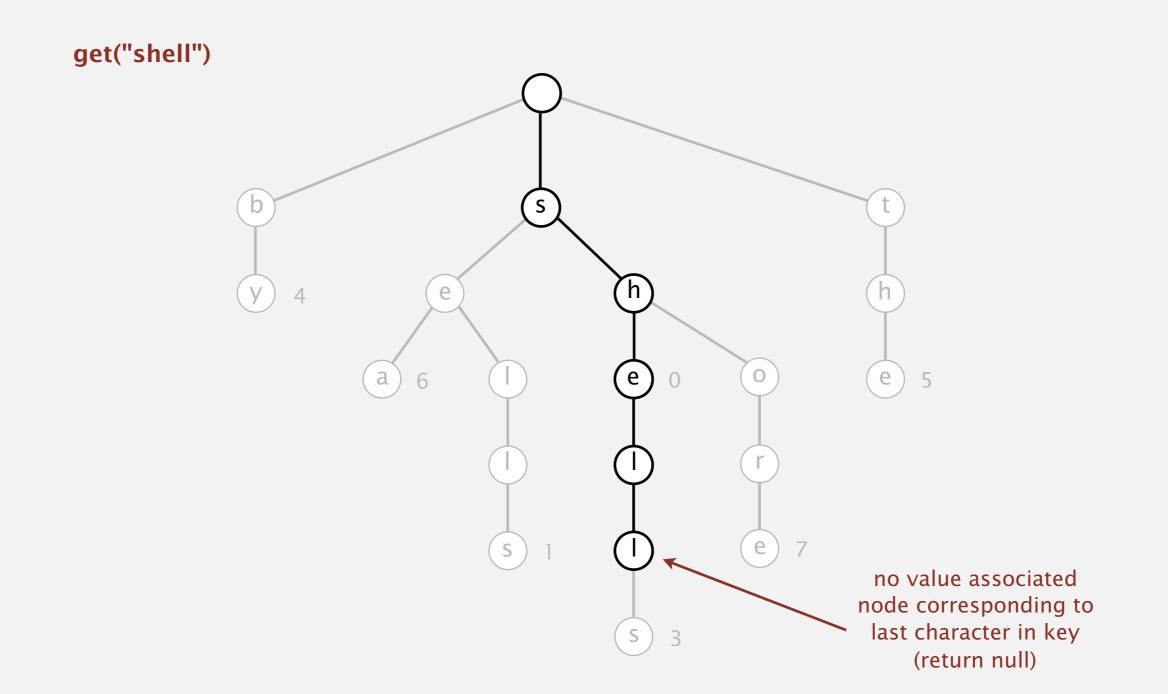

- Search hit: node where search ends has a non-null value.
- Search miss: reach null link or node where search ends has null value.

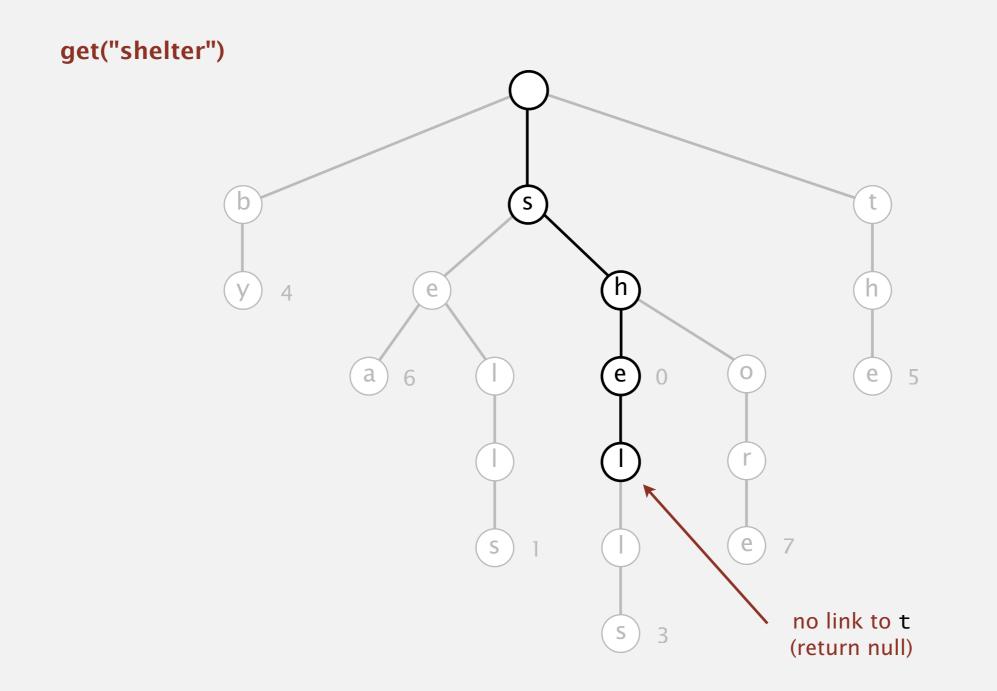

- Search hit: node where search ends has a non-null value.
- Search miss: reach null link or node where search ends has null value.

- Search hit: node where search ends has a non-null value.
- Search miss: reach null link or node where search ends has null value.

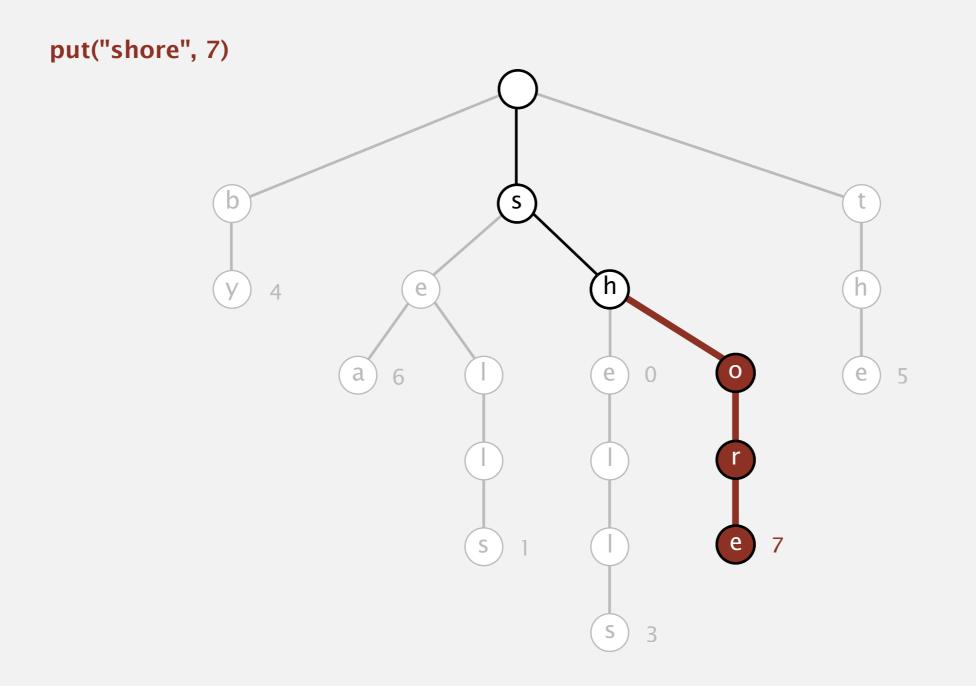

- Search hit: node where search ends has a non-null value.
- Search miss: reach null link or node where search ends has null value.

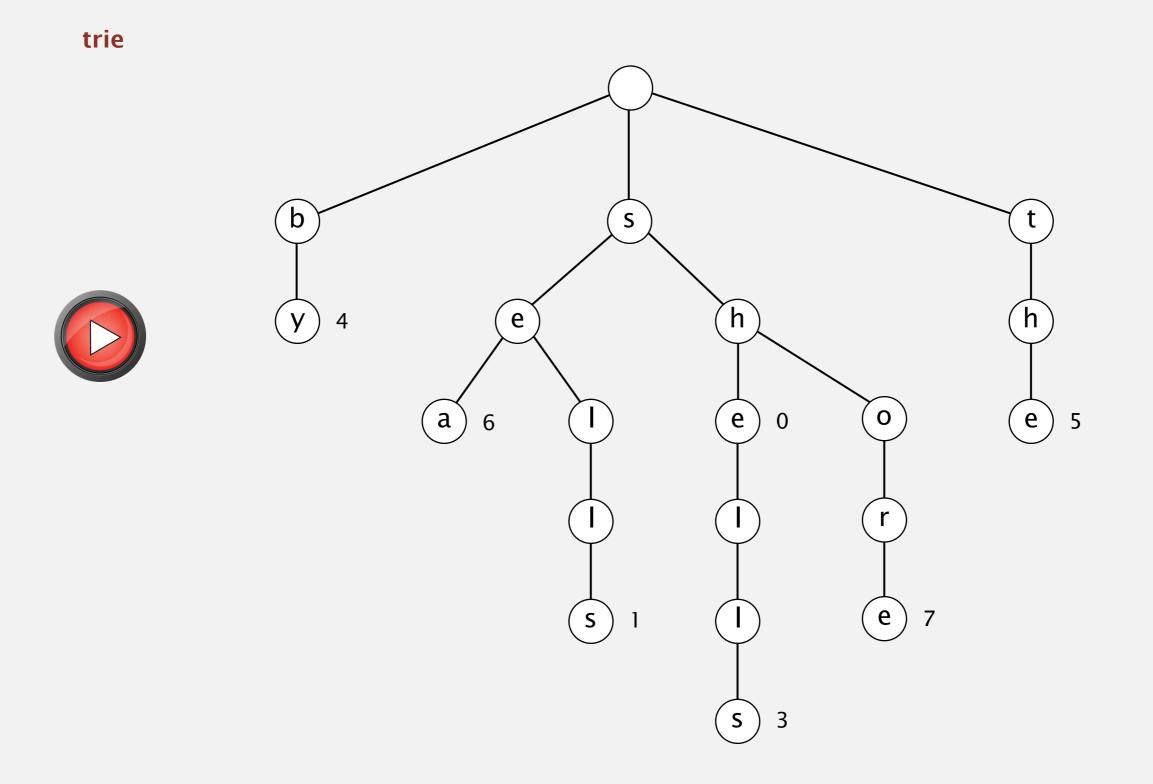

Insertion into a trie

- Encounter a null link: create new node.
- Encounter the last character of the key: set value in that node.

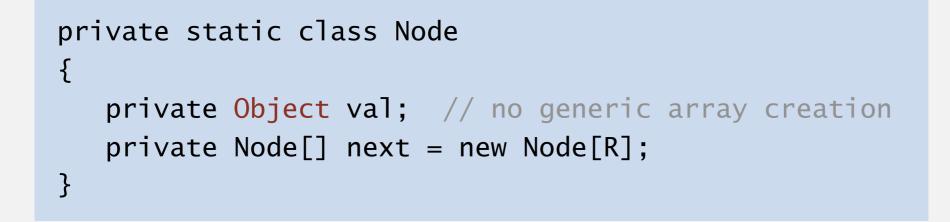

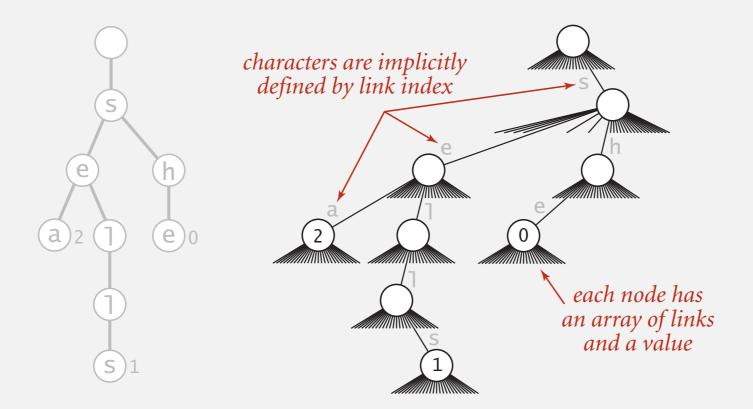

Trie construction demo

Trie representation: Java implementation

Node. A value, plus references to *R* nodes.

Remark. Neither keys nor characters are stored explicitly.

```
public class TrieST<Value>
{
   private static final int R = 256;
                                     extended ASCII
   private Node root = new Node();
   private static class Node
   { /* see previous slide */ }
  public void put(String key, Value val)
  { root = put(root, key, val, 0); }
  private Node put(Node x, String key, Value val, int d)
   {
    if (x = null) x = new Node();
    if (d == key.length()) { x.val = val; return x; }
    char c = key.charAt(d);
    x.next[c] = put(x.next[c], key, val, d+1);
    return x;
 }
```

R-way trie: Java implementation (continued)

```
public Value get(String key)
{
    Node x = get(root, key, 0);
    if (x == null) return null;
    return (Value) x.val; // cast needed
}
```

```
private Node get(Node x, String key, int d)
{
    if (x == null) return null;
    if (d == key.length()) return x;
    char c = key.charAt(d);
    return get(x.next[c], key, d+1);
}
```

}

What is order of growth of the running time (in the worst case) to insert a key into an *R*-way trie?

Α.	L	
B.	R + L	<i>R</i> = alphabet size
		<i>L</i> = length of key
С.	n + L	<i>n</i> = number of keys
D.	R L	

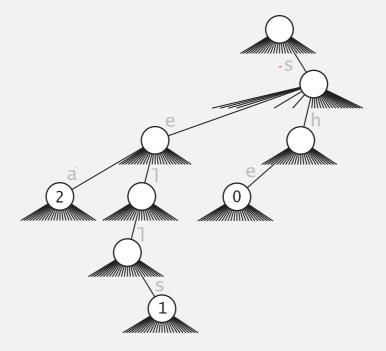

Search hit. Need to examine all *L* characters for equality.

Search miss.

- Could have mismatch on first character.
- Typical case: examine only a few characters (sublinear).

Space. *R* null links at each leaf.

(but sublinear space possible if many strings share long common prefixes)

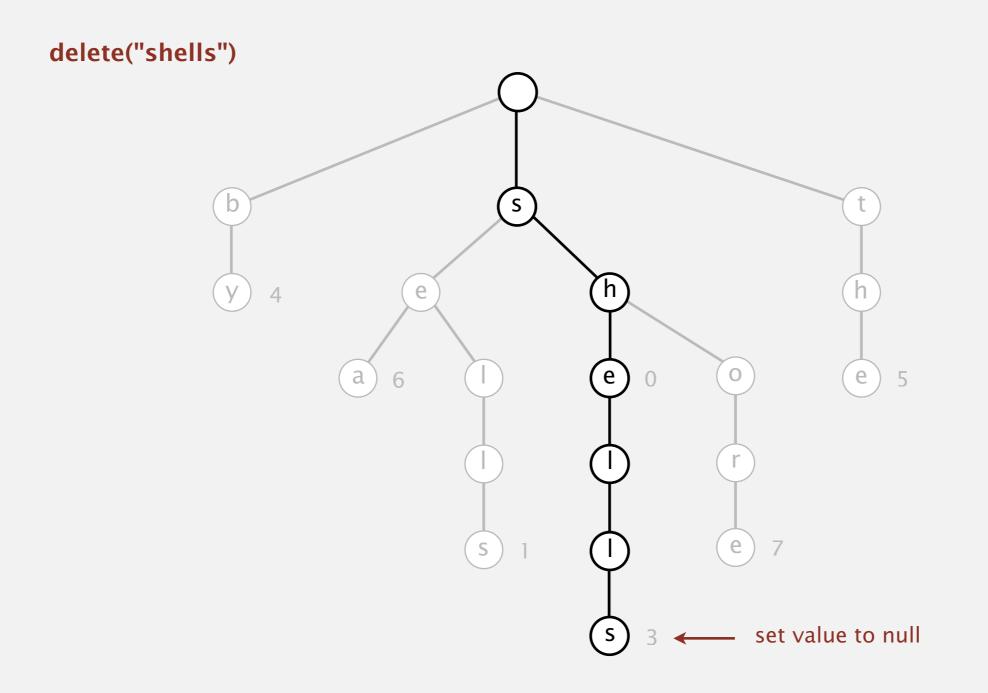

Bottom line. Fast search hit and even faster search miss, but wastes space.

Deletion in an R-way trie

To delete a key-value pair:

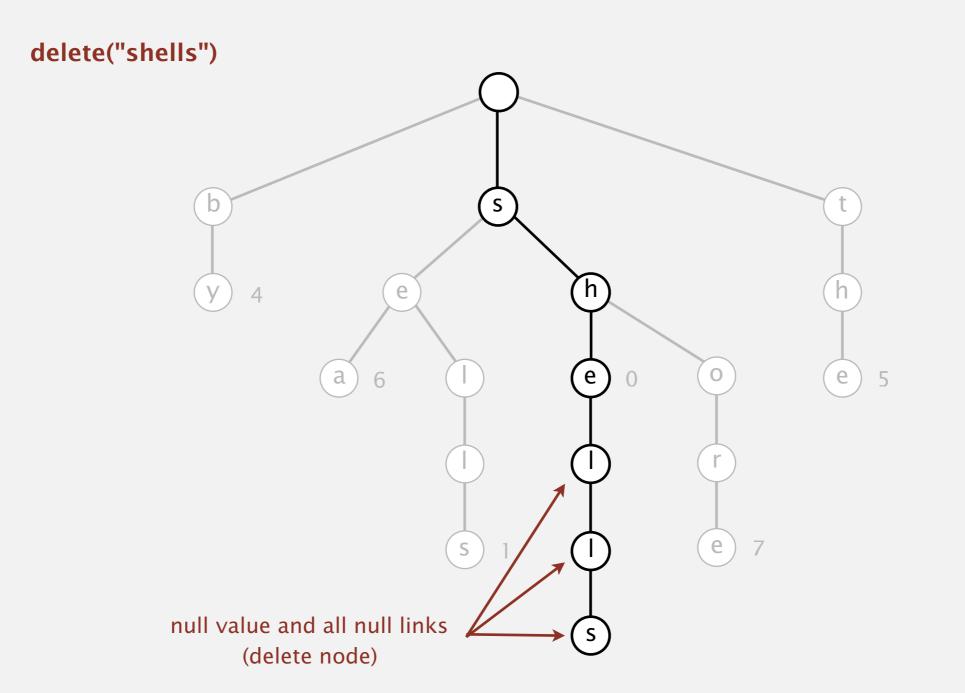

- Find the node corresponding to key and set value to null.
- If node has null value and all null links, remove that node (and recur).

Deletion in an R-way trie

To delete a key-value pair:

- Find the node corresponding to key and set value to null.
- If node has null value and all null links, remove that node (and recur).

	character accesses (typical case)				dedup	
implementation	search hit	search miss	insert	space (references)	moby.txt	actors.txt
red-black BST	$L + c \lg^2 n$	<i>c</i> lg ² <i>n</i>	$c \lg^2 n$	4 <i>n</i>	1.4	97.4
hashing (linear probing)	L	L	L	4 n to 16 n	0.76	40.6
R-way trie	L	$\log_R n$	R + L	(<i>R</i> +1) <i>n</i>	1.12	out of memory

R-way trie.

- Method of choice for small *R*.
- Works well for medium *R*.
- Too much memory for large *R*.

Challenge. Use less memory, e.g., a 65,536-way trie for Unicode!

5.2 TRIES

R-way tries

ternary search tries

character-based operations

Algorithms

ROBERT SEDGEWICK | KEVIN WAYNE

http://algs4.cs.princeton.edu

Ternary search tries

- Store characters and values in nodes (not keys).
- Each node has 3 children: smaller (left), equal (middle), larger (right).

Fast Algorithms for Sorting and Searching Strings

Jon L. Bentley* Robert Sedgewick#

Abstract

We present theoretical algorithms for sorting and searching multikey data, and derive from them practical C implementations for applications in which keys are character strings. The sorting algorithm blends Quicksort and radix sort; it is competitive with the best known C sort codes. The searching algorithm blends tries and binary search trees; it is faster than hashing and other commonly used search methods. The basic ideas behind the algo-

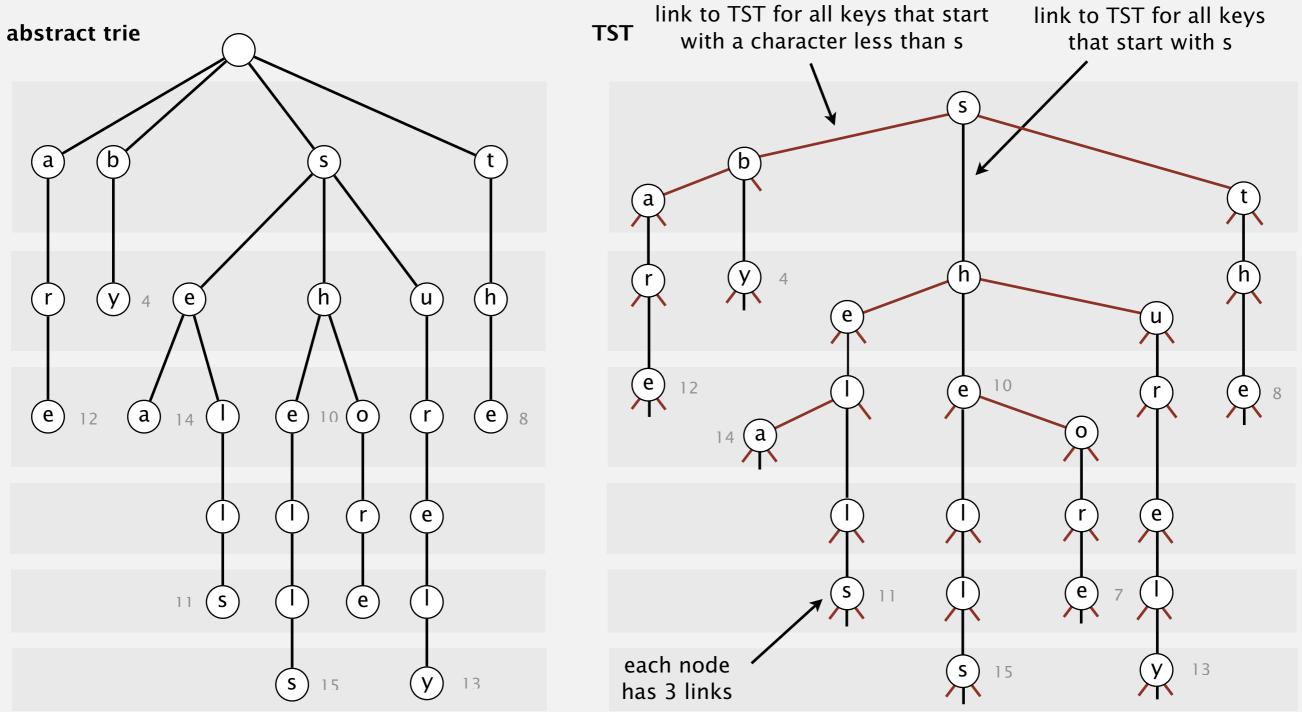

that is competitive with the most efficient string sorting programs known. The second program is a symbol table implementation that is faster than hashing, which is commonly regarded as the fastest symbol table implementation. The symbol table implementation is much more space-efficient than multiway trees, and supports more advanced searches.

In many application programs, sorts use a Quicksort implementation based on an abstract compare operation,

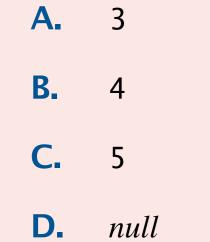

Ternary search tries

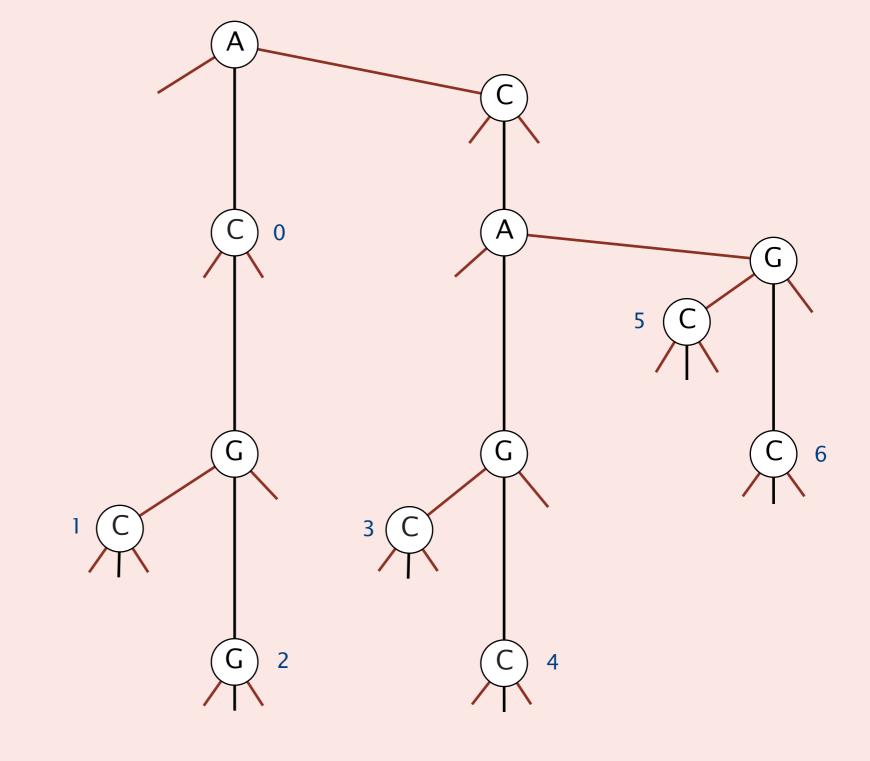

- Store characters and values in nodes (not keys).
- Each node has 3 children: smaller (left), equal (middle), larger (right).

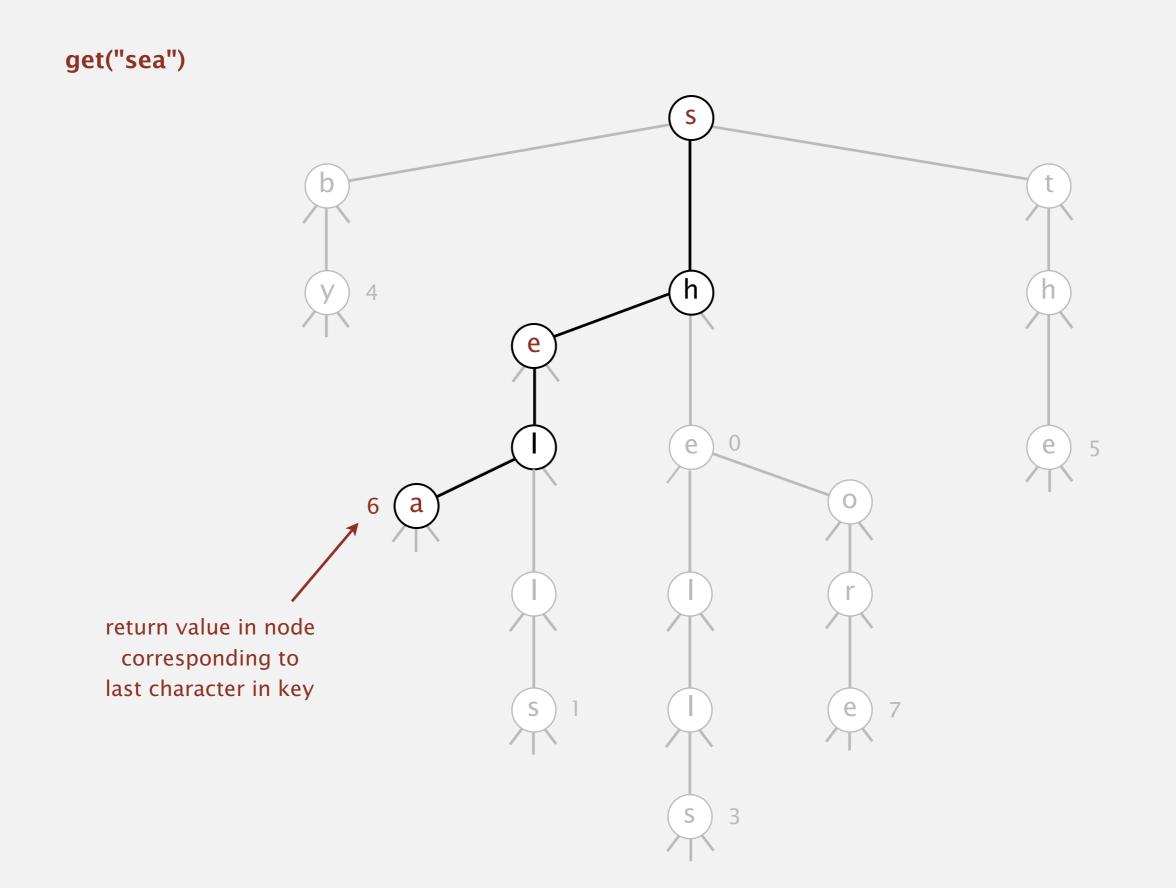

Trie quiz 2

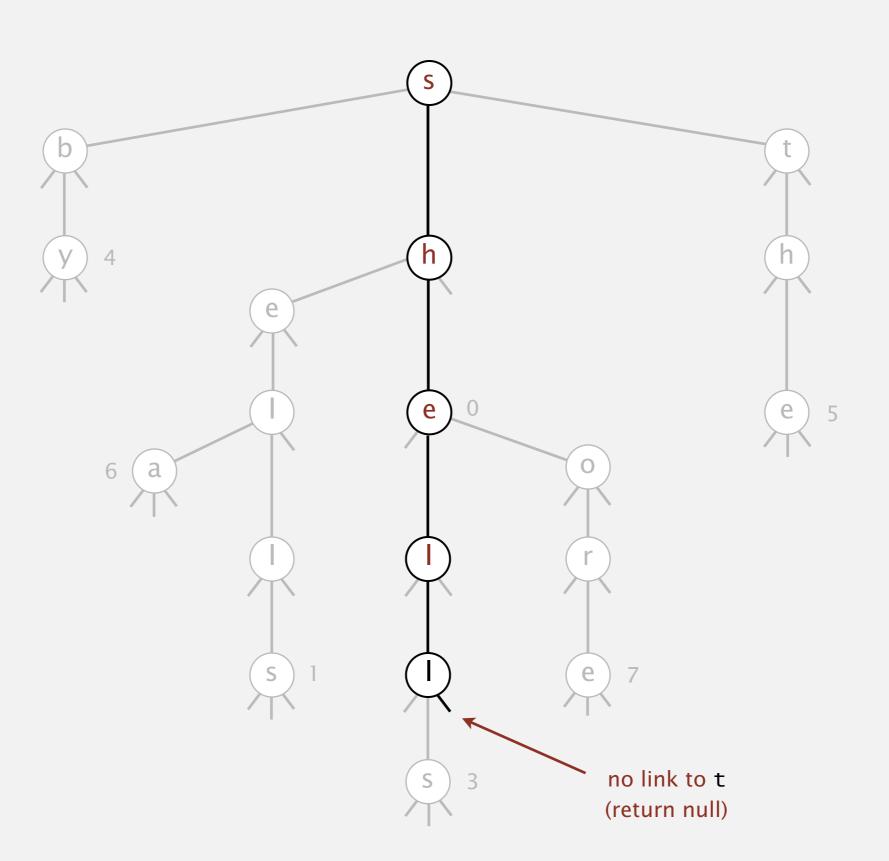

Which value is associated with the key CAC ?

get("shelter")

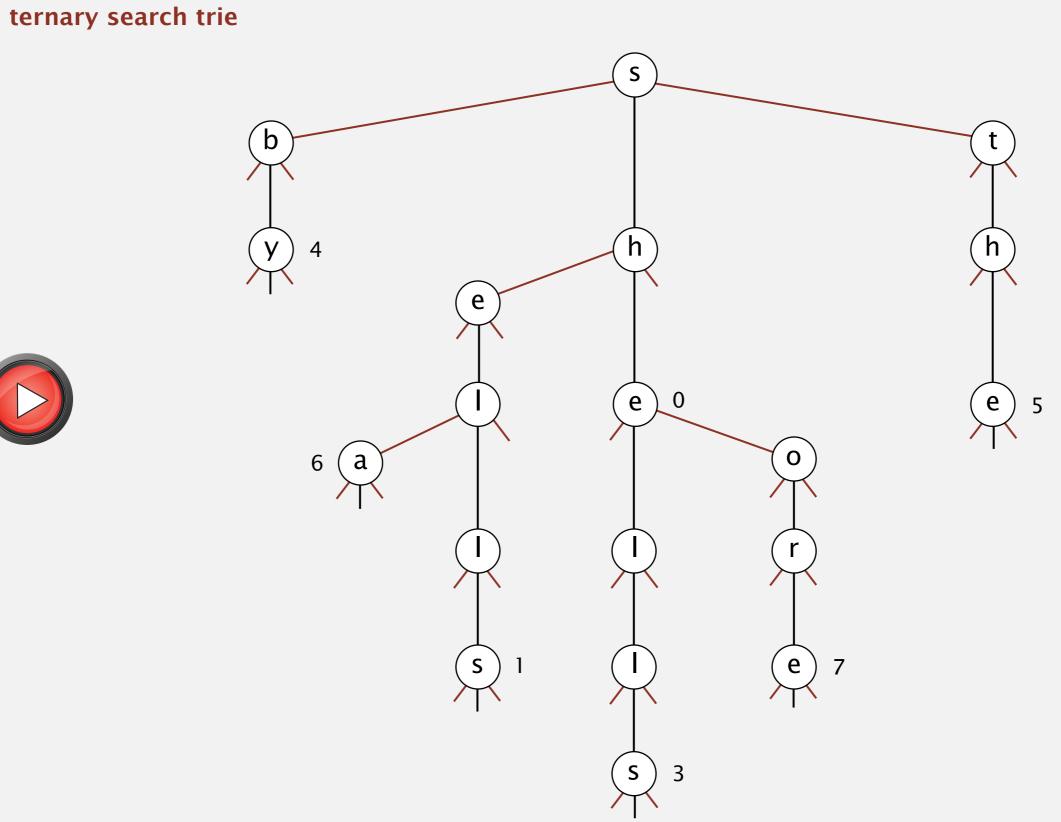

Search in a TST

Follow links corresponding to each character in the key.

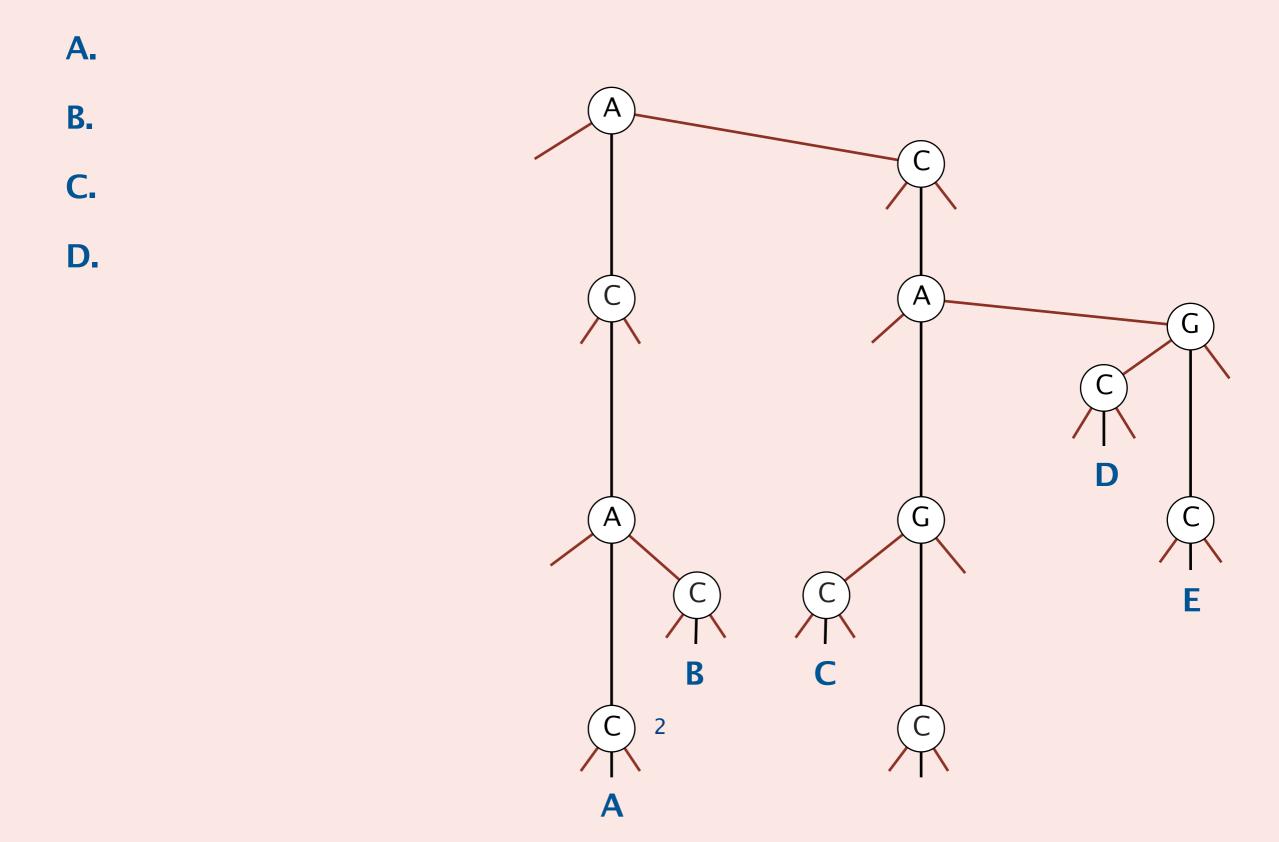

- If less, take left link; if greater, take right link.
- If equal, take the middle link and move to the next key character.

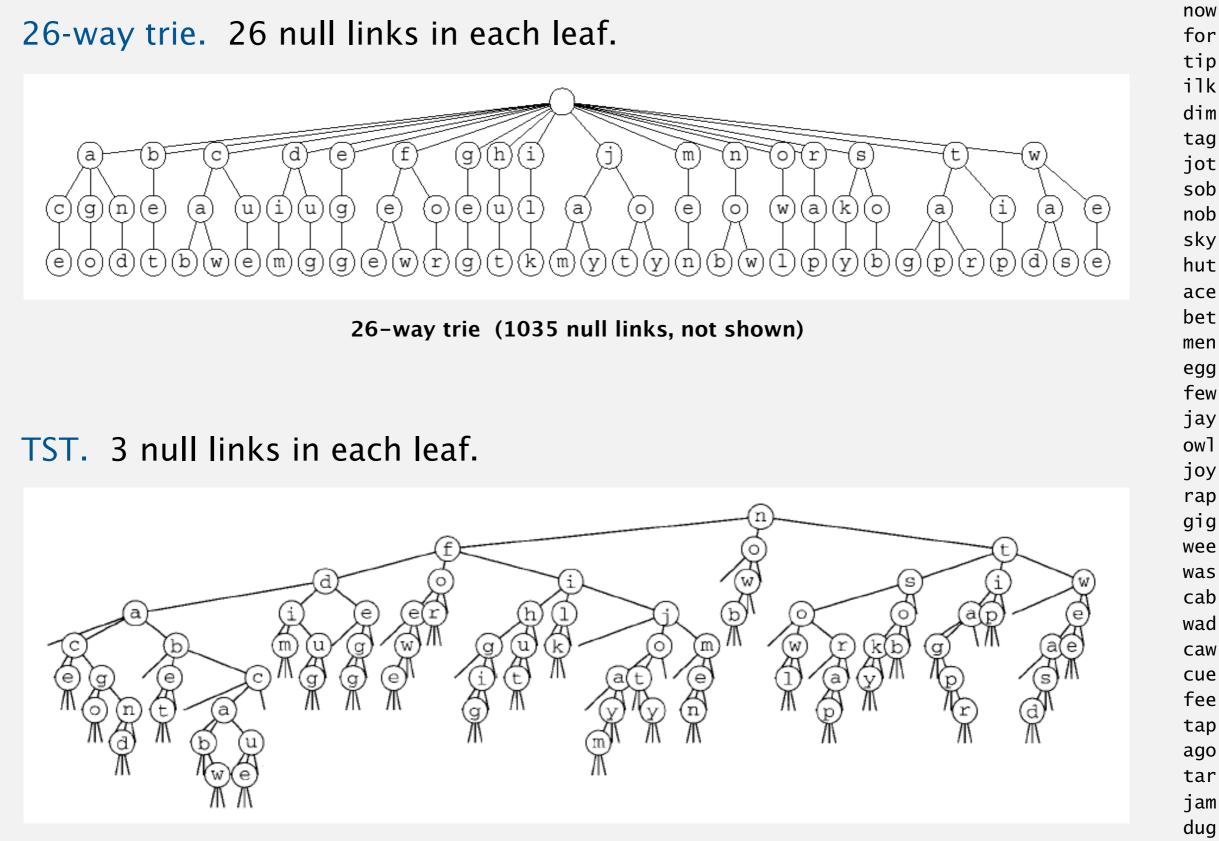

Search hit. Node where search ends has a non-null value. Search miss. Reach a null link or node where search ends has null value.

Trie quiz 3

In which subtrie would the key CCC be inserted?

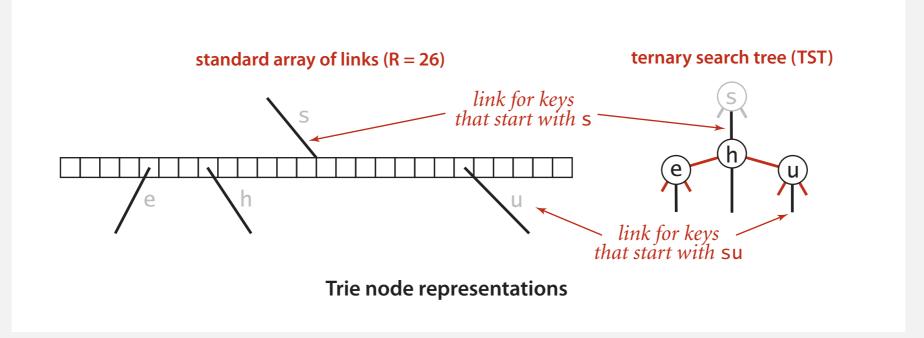

and

A TST node is five fields:

- A value.
- A character.
- A reference to a left TST.
- A reference to a middle TST.
- A reference to a right TST.

```
private class Node
{
    private Value val;
    private char c;
    private Node left, mid, right;
}
```

}

```
public class TST<Value>
{
   private Node root;
   private class Node
   { /* see previous slide */ }
   public Value get(String key)
   {
     Node x = get(root, key, 0);
      if (x == null) return null;
      return x.val;
   }
  private Node get(Node x, String key, int d)
   {
     if (x == null) return null;
     char c = key.charAt(d);
     if (c < x.c) return get(x.left, key, d);</pre>
     else if (c > x.c) return get(x.right, key, d);
     else if (d < key.length() - 1) return get(x.mid, key, d+1);</pre>
     else
                                   return x;
   }
```

```
public void put(String Key, Value val)
{ /* similar, see book or booksite */ }
```

	character accesses (typical case)				dedup	
implementation	search hit	search miss	insert	space (references)	moby.txt	actors.txt
red-black BST	$L + c \lg^2 n$	$c \lg^2 n$	$c \lg^2 n$	4 n	1.4	97.4
hashing (linear probing)	L	L	L	4 n to 16 n	0.76	40.6
R-way trie	L	$\log_R n$	R + L	(R +1) n	1.12	out of memory
TST	$L + \ln n$	ln <i>n</i>	$L + \ln n$	(4n)	0.72	38.7

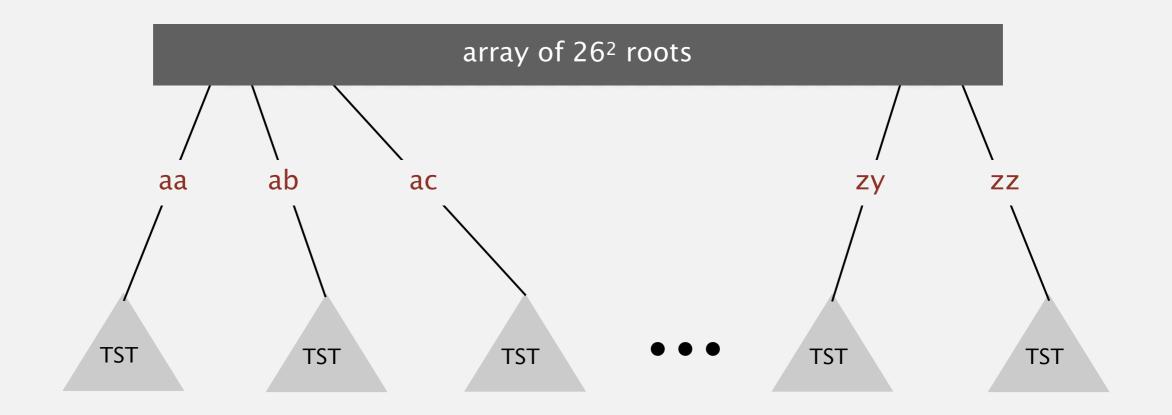

Remark. Can build balanced TSTs via rotations to achieve $L + \log n$ worst-case guarantees.

Bottom line. TST is as fast as hashing (for string keys), space efficient.

TST with R² branching at root

Hybrid of R-way trie and TST.

- Do R²-way branching at root.
- Each of R² root nodes points to a TST.

Q. What about one- and two-letter words?

	character accesses (typical case)			dedup		
implementation	search hit	search miss	insert	space (references)	moby.txt	actors.txt
red-black BST	$L + c \lg^2 n$	$c \lg^2 n$	$c \lg^2 n$	4 <i>n</i>	1.4	97.4
hashing (linear probing)	L	L	L	4n to 16n	0.76	40.6
R-way trie	L	$\log_R n$	R + L	(<i>R</i> +1) <i>n</i>	1.12	out of memory
TST	$L + \ln n$	ln <i>n</i>	$L + \ln n$	4 n	0.72	38.7
TST with R ²	$L + \ln n$	ln <i>n</i>	$L + \ln n$	$4 n + R^2$	0.51	32.7

Bottom line. Faster than hashing for our benchmark client.

TST vs. hashing

Hashing.

- Need to examine entire key.
- Search hits and misses cost about the same.
- Performance relies on hash function.
- Does not support ordered symbol table operations.

TSTs.

- Works only for string (or digital) keys.
- Search miss may involve only a few characters.
- Supports ordered symbol table operations (plus extras!).

Bottom line. TSTs are:

- Faster than hashing (especially for search misses).
- More flexible than red-black BSTs. [stay tuned]

5.2 TRIES

R-way tries

ternary search tries

Algorithms

character-based operations

ROBERT SEDGEWICK | KEVIN WAYNE

http://algs4.cs.princeton.edu

Character-based operations. The string symbol table API supports several useful character-based operations.

key	value	
by	4	
sea	6	
sells	1	
she	0	
shells	3	
shore	7	
the	5	

Prefix match. Keys with prefix sh: she, shells, and shore. Longest prefix. Key that is the longest prefix of shellsort: shells.

String symbol table API

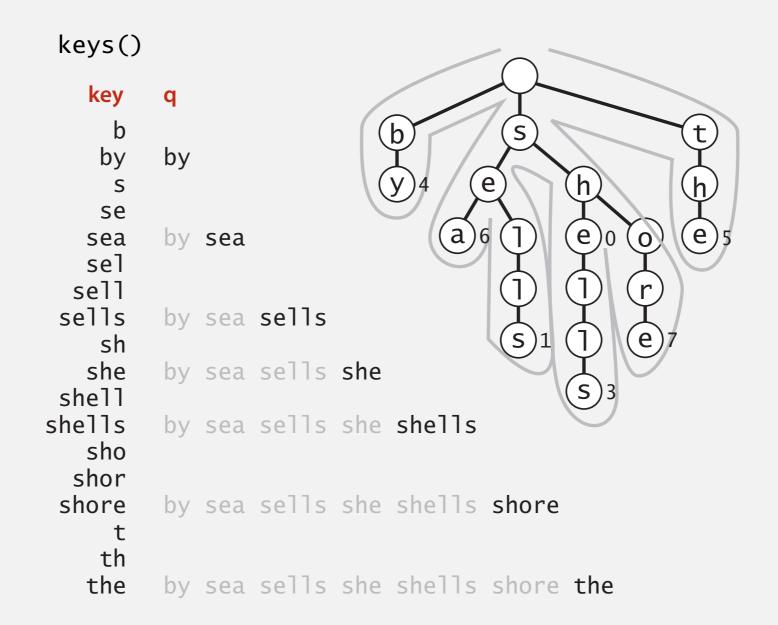

public class	StringST <value></value>		
	StringST()	create a symbol table with string keys	
void	put(String key, Value val)	put key-value pair into the symbol table	
Value	get(String key)	value paired with key	
void	delete(String key)	delete key and corresponding value	
	•		
Iterable <string></string>	keys()	all keys	
Iterable <string></string>	<pre>keysWithPrefix(String s)</pre>	keys having s as a prefix	
String	<pre>longestPrefixOf(String s)</pre>	longest key that is a prefix of s	

Remark. Can also add other ordered ST methods, e.g., floor() and rank().

Warmup: ordered iteration

To iterate through all keys in sorted order:

- Do inorder traversal of trie; add keys encountered to a queue.
- Maintain sequence of characters on path from root to node.

Ordered iteration: Java implementation

To iterate through all keys in sorted order:

- Do inorder traversal of trie; add keys encountered to a queue.
- Maintain sequence of characters on path from root to node.

```
public Iterable<String> keys()
{
   Queue<String> queue = new Queue<String>();
   collect(root, "", queue);
   return queue;
                                               sequence of characters
                                                on path from root to x
}
private void collect(Node x, String prefix, Queue<String> queue)
ł
   if (x == null) return;
   if (x.val != null) queue.enqueue(prefix);
   for (char c = 0; c < R; c++)
      collect(x.next[c], prefix + c, queue);
}
                                        or use StringBuilder
```

Prefix matches

Find all keys in a symbol table starting with a given prefix.

Ex. Autocomplete in a cell phone, search bar, text editor, or shell.

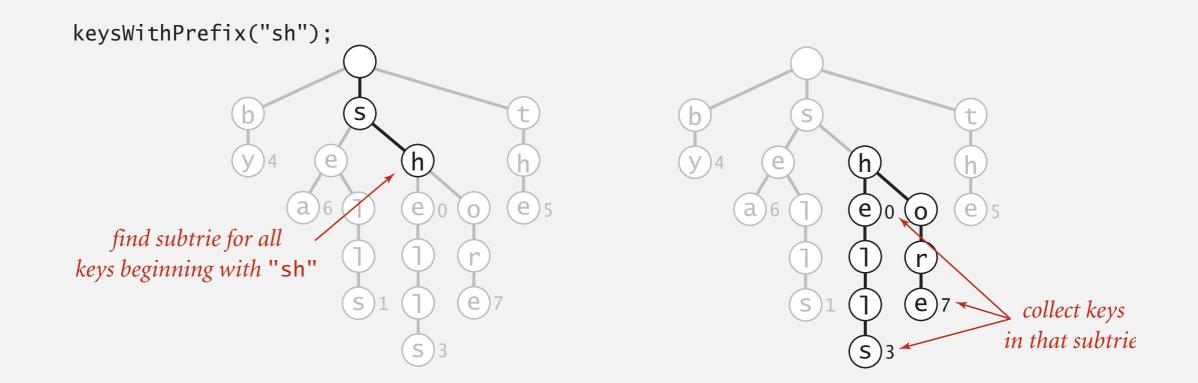

- User types characters one at a time.
- System reports all matching strings.

JOOgle	why is my comp			
0	why is my computer so slow			
	why is my computer slow			
	why is my computer so slow all of a sudden			
	why is my computer so loud			
	why is my computer running so slowly			
	why is my computer screen so big			
	why is my computer freezing			
	why is my computer beeping			
	why is my computer slowing down			
	why is my computer so slow lately			
	Google Search I'm Feeling Lucky			

Prefix matches in an R-way trie

Find all keys in a symbol table starting with a given prefix.

<pre>public Iterable<string> keysWithPrefix(String prefix)</string></pre>	key	queue
<pre>{ Queue<string> queue = new Queue<string>(); Node x = get(root, prefix, 0); collect(x, prefix, queue); } </string></string></pre>	sh she shel shell shells sho	she she shells
return queue; } root of subtrie for all strings beginning with given prefix	shor shore	she shells shore

Find longest key in symbol table that is a prefix of query string.

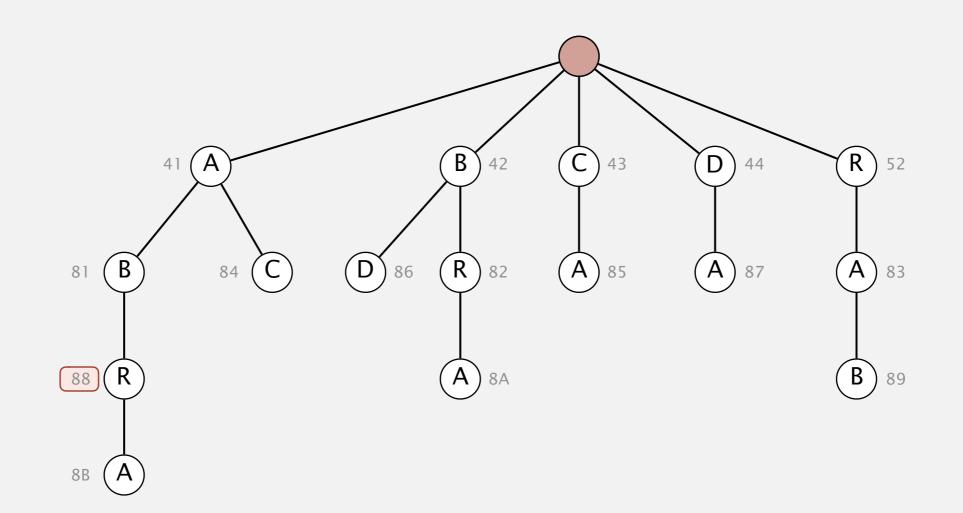

Ex 1. To send packet toward destination IP address, router chooses IP address in routing table that is longest prefix match.

"128" "128.112"	←	represented as 32-bit binary number for IPv4 (instead of string)
"128.112.055"		
"128.112.055.1	.5''	
"128.112.136"		<pre>longestPrefix0f("128.112.136.11") = "128.112.136"</pre>
"128.112.155.1	.1"	<pre>longestPrefix0f("128.112.100.16") = "128.112" longestPrefix0f("128.166.123.45") = "128"</pre>
"128.112.155.1	.3''	
"128.222"		
"128.222.136"		

Note. Not the same as floor: floor("128.112.100.16") = "128.112.055.15"

Find longest key in symbol table that is a prefix of query string.

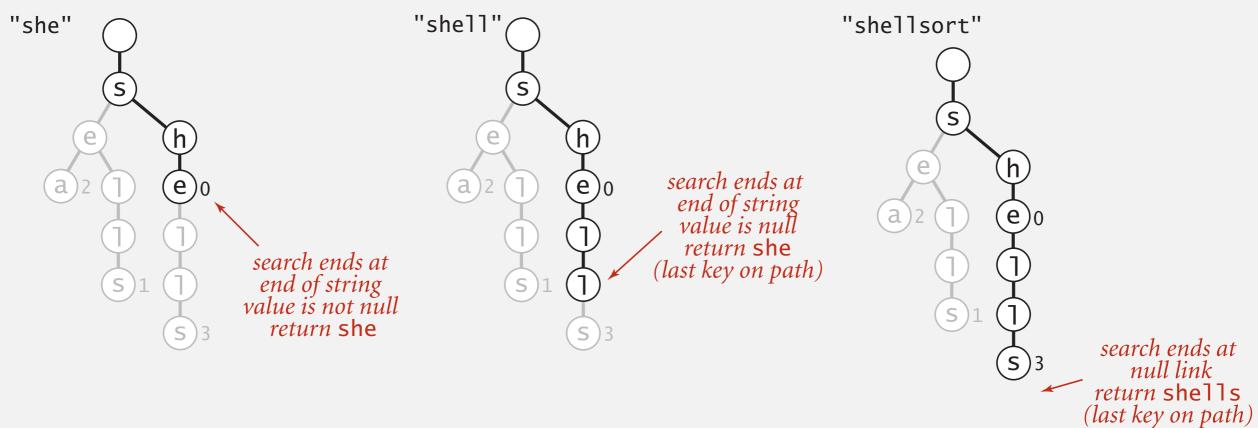

Longest prefix in an R-way trie

Find longest key in symbol table that is a prefix of query string.

- Search for query string.
- Keep track of longest key encountered.

Possibilities for longestPrefixOf()

Longest prefix in an R-way trie: Java implementation

Find longest key in symbol table that is a prefix of query string.

- Search for query string.
- Keep track of longest key encountered.

```
public String longestPrefixOf(String query)
{
   int length = search(root, query, 0, 0);
   return query.substring(0, length);
}
private int search(Node x, String query, int d, int length)
{
   if (x == null) return length;
   if (x.val != null) length = d;
   if (d == query.length()) return length;
   char c = query.charAt(d);
   return search(x.next[c], query, d+1, length);
}
```

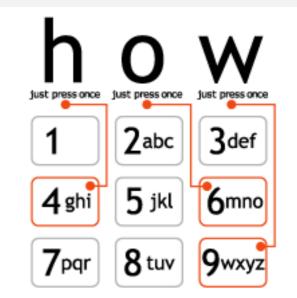

Goal. Type text messages on a phone keypad.

Multi-tap input. Enter a letter by repeatedly pressing a key. Ex. good: 4 6 6 6 6 6 6 3

"a much faster and more fun way to enter text"

T9 text input.

- Find all words that correspond to given sequence of numbers.
 4663: good, home, gone, hoof. ← textonyms
- Press * to select next option.
- Press 0 to see all completion options.
- System adapts to user's tendencies.

http://www.t9.com

Q. How to implement T9 texting on a mobile phone?

1	2 ABC	3 DEF	-
4 GHI	5 jkl	6 MNO	•
7 prqs	8 TUV	9 wxyz	Ř
× # (0 +	Ľ	Next

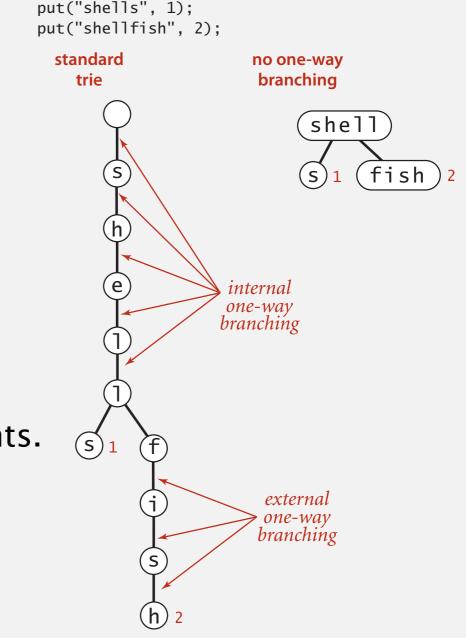

Patricia trie

Patricia trie. [Practical Algorithm to Retrieve Information Coded in Alphanumeric]

- Remove one-way branching.
- Each node represents a sequence of characters.
- Implementation: one step beyond this course.

Applications.

- Database search.
- P2P network search.
- IP routing tables: find longest prefix match.
- Compressed quad-tree for *n*-body simulation.
- Efficiently storing and querying XML documents.

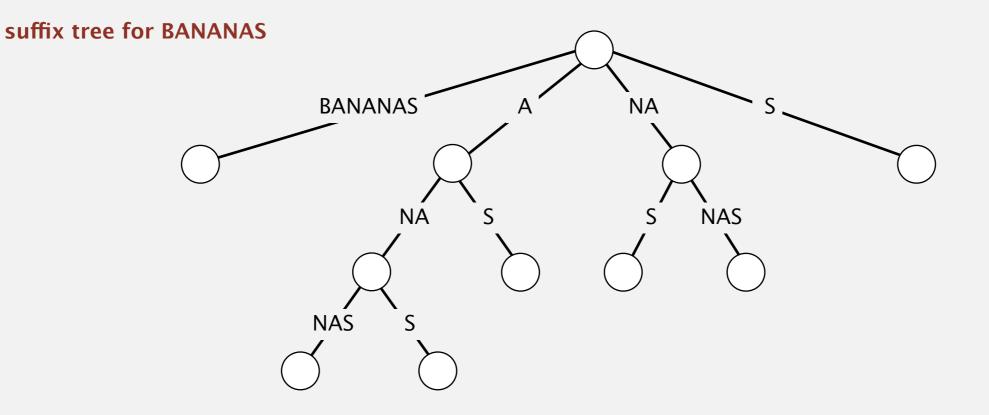

Also known as: crit-bit tree, radix tree.

Suffix tree

Suffix tree.

- Patricia trie of suffixes of a string.
- Linear-time construction: well beyond scope of this course.

Applications.

- Linear-time: longest repeated substring, longest common substring, longest palindromic substring, substring search, tandem repeats,
- Computational biology databases (BLAST, FASTA).

A success story in algorithm design and analysis.

Red-black BST.

- Performance guarantee: $\log n$ key compares.
- Supports ordered symbol table API.

Hash tables.

- Performance guarantee: constant number of probes.
- Requires good hash function for key type.

Tries. R-way, TST.

- Performance guarantee: $\log n$ characters accessed.
- Supports character-based operations.
