**Consensus and Paxos**

COS 418: Distributed Systems  
Lecture 12  
Michael Freedman

---

**Recall the use of Views**

- Let different replicas assume role of primary over time
- System moves through a sequence of views
- How do the nodes agree on view / primary?

---

**Consensus**

Definition:

1. A general agreement about something
2. An idea or opinion that is shared by all the people in a group

Origin: Latin, from *consentire*

---

**Consensus**

Given a set of processors, each with an initial value:

- **Termination:** All non-faulty processes eventually decide on a value
- **Agreement:** All processes that decide do so on the same value
- **Validity:** The value that has been decided must have proposed by some process
Consensus used in systems

Group of servers attempting:
• Make sure all servers in group receive the same updates in the same order as each other
• Maintain own lists (views) on who is a current member of the group, and update lists when somebody leaves/fails
• Elect a leader in group, and inform everybody
• Ensure mutually exclusive (one process at a time only) access to a critical resource like a file

Step one: Define your system model

• Network model:
  – Synchronous (time-bounded delay) or asynchronous (arbitrary delay)
  – Reliable or unreliable communication
  – Unicast or multicast communication
• Node failures:
  – Fail-stop (correct/dead) or Byzantine (arbitrary)

Consensus is impossible

… abandon hope, all ye who enter here …
“FLP” result

- No deterministic 1-crash-robust consensus algorithm exists for asynchronous model

- Holds even for “weak” consensus (i.e., only some process needs to decide, not all)

- Holds even for only two states: 0 and 1

Main technical approach

- Initial state of system can end in decision “0” or “1”

- Consider 5 processes, each in some initial state

  \[
  \begin{array}{l}
  [1,1,1,1,1] \rightarrow 1 \\
  [1,1,1,1,0] \rightarrow 1 \\
  [1,1,0,0,0] \rightarrow 1 \\
  [1,0,0,0,0] \rightarrow 0
  \end{array}
  \]

Main technical approach

- Goal: Consensus holds in face of 1 failure

  One of these configs must be “bi-valent” (i.e., undecided):
  Both futures possible

  \[
  \begin{array}{l}
  [1,1,0,0,0] \rightarrow 1 | 0 \\
  [1,1,0,0,0] \rightarrow 0
  \end{array}
  \]
Main technical approach

- Goal: Consensus holds in face of 1 failure

\[
\begin{align*}
[1,1,0,0] & \rightarrow 1 \\
[1,1,0,0] & \rightarrow 0 \mid 1
\end{align*}
\]

- Inherent non-determinism from asynchronous network
- Key result: All bi-valent states can remain in bi-valent states after performing some work

You won’t believe this one trick!

1. System thinks process \( p \) crashes, adapts to it…
2. But then \( p \) recovers and \( q \) crashes…
3. Needs to wait for \( p \) to rejoin, because can only handle 1 failure, which takes time for system to adapt …
4. … repeat ad infinitum …

All is not lost…

- But remember
  - “Impossible” in the formal sense, i.e., “there does not exist”
  - Even though such situations are extremely unlikely …
- Circumventing FLP Impossibility
  - Probabilistically
  - Randomization
  - Partial Synchrony (e.g., “failure detectors”)

Why should you care?

Werner Vogels, Amazon CTO

Job openings in my group

What kind of things am I looking for in you?

“You know your distributed systems theory: You know about logical time, snapshots, stability, message ordering, but also acid and multi-level transactions. You have heard about the FLP impossibility argument. You know why failure detectors can solve it (but you do not have to remember which one diamond-w was). You have at least once tried to understand Paxos by reading the original paper.”
**Paxos**

- **Safety**
  - Only a single value is chosen
  - Only a proposed value can be chosen
  - Only chosen values are learned by processes

- **Liveness ***
  - Some proposed value *eventually* chosen if fewer than half of processes fail
  - If value is chosen, a process eventually learns it

---

**Roles of a Process**

- Three conceptual roles
  - **Proposers** propose values
  - **Acceptors** accept values, where chosen if majority accept
  - **Learners** learn the outcome (chosen value)

- In reality, a process can play any/all roles

---

**Strawman**

- 3 proposers, 1 acceptor
  - Acceptor accepts first value received
  - No liveness on failure

- 3 proposals, 3 acceptors
  - Accept first value received, acceptors choose common value known by majority
  - But no such majority is guaranteed

---

**Paxos**

- Each acceptor accepts *multiple proposals*
  - Hopefully one of multiple accepted proposals will have a majority vote (and we determine that)
  - If not, rinse and repeat (more on this)

- How do we select among multiple proposals?

- **Ordering:** proposal is tuple \((n, v)\)
  - Proposal \# strictly increasing, globally unique
  - Globally unique? Trick: set low-order bits to proposer’s ID
Paxos Protocol Overview

- **Proposers:**
  1. Choose a proposal number \( n \)
  2. Ask acceptors if any accepted proposals with \( n_a < n \)
  3. If existing proposal \( v_a \) returned, propose same value \( (n, v_a) \)
  4. Otherwise, propose own value \( (n, v) \)

  *Note altruism:* goal is to reach consensus, not "win"

- **Accepters** try to accept value with highest proposal \( n \)

- **Learners** are passive and wait for the outcome

---

Paxos Phase 1

- **Proposer:**
  - Choose proposal number \( n \), send \(<\text{prepare}, n>\) to acceptors

- **Acceptors:**
  - If \( n > n_h \)
    1. \( n_h = n \) ← promise not to accept any new proposals \( n' < n \)
    2. If no prior proposal accepted
      - Reply \(<\text{promise}, n, \emptyset>\)
    3. Else
      - Reply \(<\text{promise}, n, (n_a, v_a)>\)
  - Else
    1. Reply \(<\text{prepare-failed}>\)

---

Paxos Phase 2

- **Proposer:**
  - If receive promise from majority of acceptors,
    1. Determine \( v_a \) returned with highest \( n_a \), if exists
    2. Send \(<\text{accept}, (n, v_a || v)>\) to acceptors

- **Acceptors:**
  - Upon receiving \( (n, v) \), if \( n \geq n_h \)
    1. Accept proposal and notify learner(s)
      - \( n_a = n_h = n \)
      - \( v_a = v \)

---

Paxos Phase 3

- **Learners** need to know which value chosen

- **Approach #1**
  - Each acceptor notifies all learners
  - More expensive

- **Approach #2**
  - Elect a “distinguished learner”
  - Acceptors notify elected learner, which informs others
  - Failure-prone
**Paxos: Well-behaved Run**

- If a proposal with value $v$ is decided, then every higher-numbered proposal issued by any proposer has value $v$.

**Paxos is safe**

- Intuition: if proposal with value $v$ decided, then every higher-numbered proposal issued by any proposer has value $v$.

**Race condition leads to liveness problem**

- Process 0
  - Completes phase 1 with proposal $n_0$
  - Performs phase 2, acceptors reject
  - Restarts and completes phase 1 with proposal $n_2 > n_1$

- Process 1
  - Starts and completes phase 1 with proposal $n_1 > n_0$
  - Performs phase 2, acceptors reject

- ... can go on indefinitely ...

**Paxos with leader election**

- Simplify model with each process playing all three roles
- If elected proposer can communicate with a majority, protocol guarantees liveness
- Paxos can tolerate failures $f < N / 2$
Using Paxos in system

Leader election to decide transaction coordinator

New leader election protocol

Still have split-brain scenario!

The Paxos story...

As Paxos prospered, legislators became very busy. Parliament could no longer handle all details of government, so a bureaucracy was established. Instead of passing a decree to declare whether each lot of cheese was fit for sale, Parliament passed a decree appointing a cheese inspector to make those decisions.

Cheese inspector ≈ leader using quorum-based voting protocol

• Tells mythical story of Greek island of Paxos with “legislators” and “current law” passed through parliamentary voting protocol

• Lamport won the Turing Award in 2013
The Paxos story…

Parliament passed a decree making Δίκστρα the first cheese inspector. After some months, merchants complained that Δίκστρα was too strict and was rejecting perfectly good cheese. Parliament then replaced him by passing the decree 1375: Γωυδά is the new cheese inspector.

But Δίκστρα did not pay close attention to what Parliament did, so he did not learn of this decree right away.

There was a period of confusion in the cheese market when both Δίκστρα and Γωυδά were inspecting cheese and making conflicting decisions.

Split-brain!

The Paxos story…

To prevent such confusion, the Paxons had to guarantee that a position could be held by at most one bureaucrat at any time.

To do this, a president included as part of each decree the time and date when it was proposed.

A decree making Δίκστρα the cheese inspector might read 2716: 8:30 15 Jan 72 – Δίκστρα is cheese inspector for 3 months.

Leader gets a lease!

The Paxos story…

A bureaucrat needed to tell time to determine if he currently held a post. Mechanical clocks were unknown on Paxos, but Paxons could tell time accurately to within 15 minutes by the position of the sun or the stars.

If Δίκστρα’s term began at 8:30, he would not start inspecting cheese until his celestial observations indicated that it was 8:45.

Handle clock skew:
Lease doesn’t end until expiry + max skew

Solving Split Brain

New leader election protocol

Solution
If L isn’t part of majority electing L_{new}
L_{new} waits until L’s lease expires before accepting new ops
Next lecture: Wednesday

Consensus protocol with group membership + leader election at core
