

Artificial intelligence, machine learning, machine intelligence, natural language processing, ...

- **buzzwords, hype, real accomplishments, wishful thinking**
 - big data, deep learning, neural networks, ...
- **brief history**
- **examples**
 - classification (spam detection)
 - prediction (future prices)
 - recommendation systems (Netflix)
 - natural language processing (sentiment analysis)
 - games (chess, Go)
- **disclaimer: on this topic,
I am even less of an expert than normal.
Beware!**

Revisionist history (non-expert perspective)

- **1950s, 1960s: naive optimism about artificial intelligence**
 - checkers, chess, machine translation, theorem proving, speech recognition, image recognition, vision, ...
 - almost everything proved to be much harder than thought
- **1980s, 1990s: expert or rule-based systems**
 - domain experts write down lots of rules, computers apply them to make decisions
 - it's too hard to collect the rules, and there are too many exceptions
 - doesn't scale to large datasets or new problem domains
- **2010s: machine learning, big data, ...**
 - provide a "training set" with lots of examples correctly characterized
 - define "features" that might be relevant
 - write a program that "learns" from its successes and failures on the training data (basically by figuring out how to combine feature values)
 - turn it loose on new data

Examples of ML applications (tiny subset)

- **classification**
 - spam detection, digit recognition, optical character recognition, authorship, ...
 - image recognition, face recognition, ...
- **prediction**
 - house prices, stock prices, credit scoring, ...
 - tumor probabilities, intensive care outcomes, ...
- **recommendation systems**
 - e.g., Netflix, Amazon, Goodreads, ...
- **natural language processing (NLP)**
 - language translation
 - text to speech; speech to text
 - sentiment analysis
- **games**
 - checkers, chess, Go

Types of learning algorithms

- **supervised learning (labeled data)**
 - teach the computer how to do something with training examples
 - then let it use its new-found knowledge to do it on new examples
- **unsupervised learning (unlabeled data)**
 - let the computer learn how to do something without training data
 - use this to determine structure and patterns in data
- **reinforcement learning**
 - feedback on success or failure guides/teaches future behavior
- **recommender systems**
 - look for similarities in likes and dislikes / behaviors / ...
 - use that to predict future behaviors

Classification example: spam detection

- **rule-based: look for odd words & spellings, known bad sources, etc.**
 - V1^6R^, M0INE`/, spamRus.com, ...
- **machine learning: choose a set of features like**
 - odd spelling, weird characters, language and grammar, origin, length, ...
 - provide a training set marked "spam" or "not spam"
- **ML algorithm figures out parameter settings that let it do the best job of separating spam from not spam in the training set**
- **then apply that to real data**
- **potential problems:**
 - training set isn't good enough or big enough
 - and creating it is probably manual
 - "over-fitting": does a great job on training set but little else
 - spammers keep adapting so always needs new training material

Prediction example: house prices

- only one feature here: square footage
- straight line? ("linear regression")
- some kind of curve?

Housing price prediction.

Predicting the price of art

- **what features might you use?**
 - without specifying how to weight them

Clustering (learning from unlabeled data)

- **contrast with supervised learning**
 - supervised learning
 - given a set of labels, fit a hypothesis to it
 - unsupervised learning
 - try and determine structure in the data
 - clustering algorithm groups data together based on data features
- **good for**
 - market segmentation - group customers into different market segments
 - social network analysis - Facebook "smartlists"
 - topic analysis
 - authorship

Recommendation systems

- Netflix "recommended for you"
 - Netflix challenge

Neural networks, deep learning

- simulate human brain structure with artificial neurons in simple connection patterns

Natural language processing (NLP)

- **understanding text**
 - parsing, syntactic structure
 - topic modeling
 - sentiment analysis
 - text generation
- **text to speech**
- **speech to text**
- **translation**

ML / AI issues

- **algorithmic fairness**
 - results can't be better than training data
 - if that has implicit or explicit biases, results are biased
- **accountability**
 - what is the algorithm really doing?
 - can its results be explained
- **appropriate uses?**
 - prison sentencing
 - drone strikes
 - weapon systems
 - resume evaluation
 - medical decisions
 - ...
- **limitations**
 - can ML algorithms be better than their data?
