

The Design of C

“C is quirky, flawed, and an enormous success. While accidents of history surely helped, it evidently satisfied a need for a system implementation language efficient enough to displace assembly language, yet sufficiently abstract and fluent to describe algorithms and interactions in a wide variety of environments.”

-- Dennis Ritchie

Goals of this Lecture

Help you learn about:

- The decisions that were made by the designers* of C
- **Why** they made those decisions
- ... and thereby...
- The fundamentals of C

Why?

- Learning the design rationale of the C language provides a richer understanding of C itself
- A power programmer knows both the programming language and its design rationale

* Dennis Ritchie & members of standardization committees

Goals of C

Designers wanted C to:	But also:
Support system programming	Support application programming
Be low-level	Be portable
Be easy for people to handle	Be easy for computers to handle

- Conflicting goals on multiple dimensions!
- Result: different design decisions than Java

Operators

Issue: What kinds of operators should C have?

Thought process

- Should handle typical operations
- Should handle bit-level programming ("bit twiddling")
- Should provide a mechanism for converting from one type to another

Operators

Decisions

- Provide typical arithmetic operators: `+` `-` `*` `/` `%`
- Provide typical relational operators: `==` `!=` `<` `<=` `>` `>=`
 - Each evaluates to 0 \Rightarrow FALSE, 1 \Rightarrow TRUE
- Provide typical logical operators: `!` `&&` `||`
 - Each interprets 0 \Rightarrow FALSE, non-0 \Rightarrow TRUE
 - Each evaluates to 0 \Rightarrow FALSE, 1 \Rightarrow TRUE
- Provide bitwise operators: `~` `&` `|` `^` `>>` `<<`
- Provide a cast operator: `(type)`

Logical vs. Bitwise Ops

Logical AND (&&) vs. bitwise AND (&)

- 2 (TRUE) && 1 (TRUE) => 1 (TRUE)

Decimal	Binary
2	00000000 00000000 00000000 00000010
&& 1	00000000 00000000 00000000 00000001
----	-----
1	00000000 00000000 00000000 00000001

- 2 (TRUE) & 1 (TRUE) => 0 (FALSE)

Decimal	Binary
2	00000000 00000000 00000000 00000010
& 1	00000000 00000000 00000000 00000001
----	-----
0	00000000 00000000 00000000 00000000

Implication:

- Use **logical** AND to control flow of logic
- Use **bitwise** AND only when doing bit-level manipulation
- Same for OR and NOT

Assignment Operator

Issue: What about assignment?

Thought process

- Must have a way to assign a value to a variable
- Many high-level languages provide an assignment **statement**
- Would be more expressive to define an assignment **operator**
 - Performs assignment, and then *evaluates to the assigned value*
 - Allows assignment to appear within larger expressions

Decisions

- Provide assignment operator: =
- Define assignment operator so it changes the value of a variable, and also evaluates to that value

Assignment Operator Examples

Examples

```
i = 0;
    /* Side effect: assign 0 to i.
       Evaluate to 0.

j = i = 0; /* Assignment op has R to L associativity */
    /* Side effect: assign 0 to i.
       Evaluate to 0.
       Side effect: assign 0 to j.
       Evaluate to 0. */

while ((i = getchar()) != EOF) ...
    /* Read a character.
       Side effect: assign that character to i.
       Evaluate to that character.
       Compare that character to EOF.
       Evaluate to 0 (FALSE) or 1 (TRUE). */
```

Special-Purpose Assignment

Issue: Should C provide tailored assignment operators?

Thought process

- The construct `a = b + c` is flexible
- The construct `i = i + c` is somewhat common
- The construct `i = i + 1` is very common
- Special-purpose operators make code more expressive
 - Might reduce some errors
 - May complicate the language and compiler

Decisions

- Introduce `+=` operator to do things like `i += c`
- Extend to `-=` `*=` `/=` `~=` `&=` `|=` `^=` `<<=` `>>=`
- Special-case increment and decrement: `i++` `i--`
- Provide both pre- and post-inc/dec: `x = ++i`; `y = i++`;

iClicker Question

Q: What are `i` and `j` set to in the following code?

```
i = 5;  
j = i++;  
j += ++i;
```

- A. 5, 7
- B. 7, 5
- C. 7, 11
- D. 7, 12
- E. 7, 13

sizeof Operator

Issue: How to determine the sizes of data?

Thought process

- The sizes of most primitive types are un- or under-specified
- Provide a way to find size of a given variable programmatically

Decisions

- Provide a **sizeof** operator
 - Applied at compile-time
 - Operand can be a **data type**
 - Operand can be an **expression**,
from which the compiler infers a data type

Examples, on courselab using gcc217

- **sizeof(int)** evaluates to 4
- **sizeof(i)** evaluates to 4 (where **i** is a variable of type **int**)

iClicker Question

Q: What is the value of the following `sizeof` expression on the courselab machines?

```
int i = 1;  
sizeof(i + 2L)
```

- A. 3
- B. 4
- C. 8
- D. 12
- E. error

Other Operators

Issue: What other operators should C have?

Decisions

- Function call operator
 - Should mimic the familiar mathematical notation
 - `function(param1, param2, ...)`
- Conditional operator: `?:`
 - The only ternary operator: “inline if statement”
 - Example: `(i < j) ? i : j` evaluates to min of `i` and `j`
 - See King book for details
- Sequence operator: `,`
 - See King book
- Pointer-related operators: `&` `*`
 - Described later in the course
- Structure-related operators (`.` `->`)
 - Described later in the course

Operators Summary: C vs. Java

Java only

- `>>>` right shift with zero fill
- `new` create an object
- `instanceof` is left operand an object of class right operand?

C only

- `->` structure member select
- `*` dereference
- `&` address of
- `,` sequence
- `sizeof` compile-time size of

History of programming languages: goto, if-then-else, while-do

What the computer does:

```
/* add up the first n numbers */
```

1. `s = 0;`
2. `i = 1;`
3. `if (i>n) goto 7`
4. `s = s + i;`
5. `i = i + 1;`
6. `goto 3`
7. `/* answer in s */`

Early programming
languages (1950s)

```
s=0;
i=1;
LOOP: if i>n goto DONE
s=s+1;
i=i+1;
goto LOOP;
DONE:
```

Control Statements

- **Algol-60 language (1960)**
 - **if-then-else, while-do, for loop, goto**
- **Scientific background**
 - **Boehm and Jacopini proved (1966)** that any algorithm can be expressed as the nesting of only 3 control structures:

Barry Boehm

Sequence

Selection

Repetition

Control Statements (cont.)

- Thought Process (cont.)
 - **Dijkstra** argued that any algorithm **should** be expressed using only those control structures (*GOTO Statement Considered Harmful* paper, 1968)
- C language design (1972)
 - Basically follow ALGOL-60, but use { braces } instead of the more heavyweight BEGIN – END syntax.

Edsger Dijkstra

Sequence Statement

Sequence

Compound statement, alias block

```
{  
    statement1;  
    statement2;  
    ...  
}
```

Selection Statements

Selection

```
if (expr)
    statement1;
```

```
if (expr)
    statement1;
else
    statement2;
```

Selection Statements

switch and **break** statements, for multi-path decisions on a single *integerExpr*

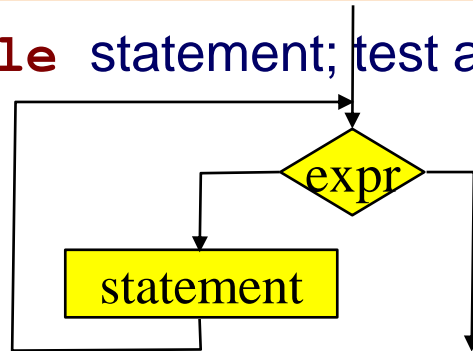

```
switch (integerExpr)
{ case integerLiteral1:
  ...
  break;
  case integerLiteral2:
  ...
  break;
  ...
  default:
  ...
}
```

What happens
if you forget
break?

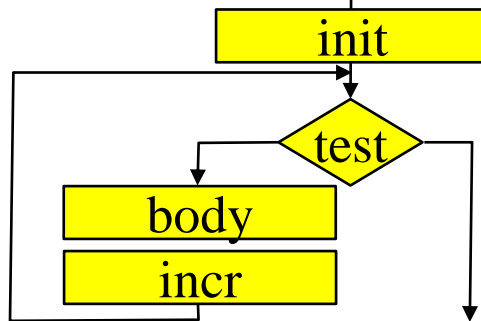

Repetition Statements

while statement; test at leading edge

```
while (expr)  
    statement;
```

for statement; test at leading edge, increment at trailing edge

```
for (initExpr; testExpr; incrExpr)  
    bodyStatement;
```

do...while statement; test at trailing edge

```
do  
    statement;  
while (expr);
```

Other Control Statements

Issue: What other control statements should C provide?

Decisions

- **break** statement (revisited)
 - Breaks out of closest enclosing `switch` or repetition statement
- **continue** statement
 - Skips remainder of current loop iteration
 - Continues with next loop iteration
 - When used within `for`, still executes *incrementExpr*
- **goto** statement grudgingly provided
 - Jump to specified **label**

Declaring Variables

Issue: Should C require variable declarations?

Thought process:

- Declaring variables allows compiler to check spelling
- Declaring variables allows compiler to allocate memory more efficiently

Declaring Variables

Decisions:

- Require variable declarations
- Provide **declaration statement**
- Programmer specifies type of variable (and other attributes too)

Examples

- `int i;`
- `int i, j;`
- `int i = 5;`
- `const int i = 5; /* value of i cannot change */`
- `static int i; /* covered later in course */`
- `extern int i; /* covered later in course */`

Declaring Variables

Decisions (cont.):

- Unlike Java, declaration statements **must** appear before any other kind of statement in compound statement

```
{  
    int i;  
    /* Non-declaration  
       stmts that use i. */  
    ...  
    int j;  
    /* Non-declaration  
       stmts that use j. */  
    ...  
}
```

Illegal in C

```
{  
    int i;  
    int j;  
    ...  
    /* Non-declaration  
       stmts that use i. */  
    ...  
    /* Non-declaration  
       stmts that use j. */  
    ...  
}
```

Legal in C

Repetition Statements

Decisions (cont.)

- Similarly, cannot declare loop control variable in `for` statement

```
{  
  ...  
  for (int i = 0; i < 10; i++)  
    /* Do something */  
  ...  
}
```

Illegal in C

```
{  
  int i;  
  ...  
  for (i = 0; i < 10; i++)  
    /* Do something */  
  ...  
}
```

Legal in C

Statements Summary: C vs. Java

Java only

- Declarations anywhere within block
- Declare immutable variables with **final**
- Conditionals of type **boolean**
- “Labeled” **break** and **continue**
- No **goto**

C only

- Declarations only at beginning block
- Declare immutable variables with **const**
- Conditionals of any type (checked for zero / nonzero)
- No “labeled” **break** and **continue**
- **goto** provided (but don't use it)

iClicker Question

Q: What does the following code print?

```
int i = 1;
switch (i++) {
    case 1: printf("%d", ++i);
    case 2: printf("%d", i++);
}
```

- A. 1
- B. 2
- C. 3
- D. 22
- E. 33

I/O Facilities

Issue: Should C provide I/O facilities?

Thought process

- Unix provides the **file** abstraction
 - A file is a sequence of characters with an indication of the current position
- Unix provides 3 standard files
 - Standard input, standard output, standard error
- C should be able to use those files, and others
- I/O facilities are complex
- C should be small/simple

I/O Facilities

Decisions

- Do not provide I/O facilities in the **language**
- Instead provide I/O facilities in **standard library**
 - **Constant:** `EOF`
 - **Data type:** `FILE` (described later in course)
 - **Variables:** `stdin`, `stdout`, and `stderr`
 - **Functions:** ...

Reading Characters

Issue: What functions should C provide for reading characters from standard input?

Thought process

- Need function to read a single character from `stdin`
- Function must have a way to indicate failure, that is, to indicate that no characters remain

Decisions

- Provide `getchar()` function
- Make return type of `getchar()` wider than `char`
 - Make it `int`; that's the natural word size
- Define `getchar()` to return `EOF` (a special non-character `int`) to indicate failure

Note

- There is no such thing as "the `EOF` character"

Writing Characters

Issue: What functions should C provide for writing a character to standard output?

Thought process

- Need function to write a single character to `stdout`

Decisions

- Provide a `putchar()` function
- Define `putchar()` to accept one parameter
 - For symmetry with `getchar()`, parameter should be an `int`

Reading Other Data Types

Issue: What functions should C provide for reading data of other primitive types?

Thought process

- Must convert external form (sequence of character codes) to internal form
- Could provide `getshort()`, `getint()`, `getfloat()`, etc.
- Could provide one parameterized function to read any primitive type of data

Decisions

- Provide `scanf()` function
- Can read any primitive type of data
- First parameter is a **format string** containing **conversion specifications**

See King book for details

Writing Other Data Types

Issue: What functions should C provide for writing data of other primitive types?

Thought process

- Must convert internal form to external form (sequence of character codes)
- Could provide `putshort()`, `putint()`, `putfloat()`, etc.
- Could provide one parameterized function to write any primitive type of data

Decisions

- Provide `printf()` function
- Can write any primitive type of data
- First parameter is a **format string** containing **conversion specifications**

See King book for details

Other I/O Facilities

Issue: What other I/O functions should C provide?

Decisions

- `fopen()`: Open a stream
- `fclose()`: Close a stream
- `fgetc()`: Read a character from specified stream
- `fputc()`: Write a character to specified stream
- `fgets()`: Read a line/string from specified stream
- `fputs()`: Write a line/string to specified stream
- `fscanf()`: Read data from specified stream
- `fprintf()`: Write data to specified stream

Described in King book, and later in the course after covering files, arrays, and strings

Summary

C design decisions and the goals that affected them

- Data types (last time)
- Operators
- Statements
- I/O facilities

Knowing the design goals and how they affected the design decisions can yield a rich understanding of C

Appendix: The Cast Operator

Cast operator has multiple meanings:

(1) Cast between integer type and floating point type:

- Compiler generates code
- At run-time, code performs conversion

f `11000001110110110000000000000000` **-27.375**

i = (int) f

i `1111111111111111111111111111111100101` **-27**

Appendix: The Cast Operator

(2) Cast between floating point types of different sizes:

- Compiler generates code
- At run-time, code performs conversion

f `11000001110110110000000000000000` **-27.375**

d = (double) f

d `11000000001110110110000000000000
00000000000000000000000000000000` **-27.375**

Appendix: The Cast Operator

(3) Cast between integer types of different sizes:

- Compiler generates code
- At run-time, code performs conversion

i 00000000000000000000000000000000000010 **2**

c = (char) i

c 00000010 **2**

Appendix: The Cast Operator

(4) Cast between integer types of same size:

- Compiler generates no code
- Compiler views given bit-pattern in a different way

`i` 111111111111111111111111111111111110 -2

`u = (unsigned int) i`

`u` 111111111111111111111111111111111110 4294967294
