# Precept 4: IPC & Process Mngmt.

COS 318: Fall 2018

---

# Project 4 Schedule

- **Precept:** Monday 11/05, 7:30pm
  - (You are here)
- **Design Review:** Monday 11/12, 3 - 7pm
- **Due:** Sunday 11/18, 11:55pm

# Project 4 Overview

- **Goal:** Add process management and inter-process communication to the kernel
- Read the project spec for details
- Starter code can be found on the lab machines (`/u/318/code/project4`)
- **Start early**

# Project 4 Overview

1. Implement a spawn system call
2. Implement inter-process communication using message boxes
3. Implement a handler for the keyboard interrupt
4. Implement a kill system call
5. Implement a wait system call

# Project 4 Implementation Checklist

1. `do_spawn`: creates a new process
2. `do_mbox_*`: mbox functions to enable IPC
  - `open`, `close`, `send`, `recv`, `is_full`
3. Handle keyboard input: `putchar`, `do_getchar`
4. `do_kill`: kills a process
5. `do_wait`: waits on a process

---

# System Calls

---

# Spawn

- Kernel has a fixed array of PCBs
- What information do you need to initialize a process?
  - PID
  - New stacks (user/stack)
  - Entry point (ramdisk\_find)
  - `total_ready_priority` (lottery scheduling)
- Scheduler uses lottery scheduling
- Make sure you keep the sum of the priorities updated

# Kill

- A process should be killed immediately
- Which queue it's in (ready, blocked, sleeping, etc.) doesn't matter – kill it!
- Do not reclaim locks (this is extra credit)
- Reclaim memory:
  - PCB
  - Stacks
  - Look at robinhood test case to determine what else needs to be reclaimed
- Update `total_ready_priority`

# Wait

- Waits for a process to terminate:
  - Blocks until the process is killed or exits normally
- What do you need to add to the PCB to implement this behavior?
- Return -1 on failure, 0 on success

---

# Message Passing + Keyboard

---

# Message Box - Overview

- Used for inter-process communication
  - Processes can both put and consume data from the message box
- It's a bounded buffer problem!
  - **send** blocks if the message box is full
  - **recv** blocks if there are no messages

# Message Box - Implementation

- Implemented as a circular buffer
  - Array, with head and tail pointers
- Receive messages in FIFO order
- Messages can have variable length
  - But, there is a fixed max length. See constants at bottom of `common.h`

# Message Box - Suggestions

- Use locks and CVs as shown in class
  - Probably need two CVs: `fullBuffer` and `emptyBuffer`
- Multiple producers + consumers: protect against race conditions
- Review [Lecture 10](#) and MOS 2.3.7-8

# Keyboard - How does it work?

- **IRQ1** interrupt generated on key press or release
- Interrupt handler gets key scan code from hardware
- Specific key handler called, based on key type:
  - Modifier Key: change internal state
  - Other Keys: convert scan code to ASCII char + post to keyboard buffer

# Keyboard - Software Design

- `kernel.c:init_idt` sets keyboard handler to `entry.S:irq1_entry`
- `irq1_entry` saves context + calls `keyboard.c:keyboard_interrupt`
- `keyboard_interrupt` gets scan code from hardware + calls specific key handler...

# Keyboard - Software Design

- Modifier keys get their own handlers
- **normal\_handler** catches everything else:
  - Converts scan code to ASCII character
  - Calls **putchar** to add it to keyboard buffer
- Processes read from buffer with **get\_char**

# Keyboard - What you need to do

- Implement `putchar` and `do_getchar`
  - Use your message box API!
- Producer should not be blocked
  - If keyboard message box is full, discard the character
  - Use `do_mbox_is_full` to check beforehand
- What if IRQ1 occurs while a process is calling `get_char`?

# Tips + Other Notes

- Synchronization is tricky: think carefully about when / how to use locks, CVs, and critical sections
- Look at `util.h` + other `.h` files for helpful functions
- May need to change other pieces of code - this is fine
  - Make sure you submit them!
- Only two test cases provided: write your own unit tests

# Design Review

- **Process Management:**

- How will your spawn, wait, and kill work?
- How will you satisfy the requirement that *if a process is killed while blocked on a lock, semaphore, condition variable or barrier, the other processes which interact with that synchronization primitive will be unaffected?*

- **Mailboxes:**

- What fields will the structs need?
- Which synchronization primitives will you use?

---

# Questions?

---
