

**EXERCISE 1: Analysis of Sorting Algorithms**

Suppose that you have an array of length  $2n$  consisting of  $n$  B's followed by  $n$  A's. Below is the array when  $n = 8$ .

B B B B B B B B A A A A A A A A

- (a) How many compares, as a function of  $n$ , does it take to sort the array in ascending order using **Selection Sort**? Use tilde notation.
- (b) How many compares, as a function of  $n$ , does it take to sort the array in ascending order using **Insertion Sort**? Use tilde notation.
- (c) How many compares, as a function of  $n$ , does it take to sort the array in ascending order using **Merge Sort**? Use tilde notation.

## EXERCISE 2: Three-Way Merge Sort

3-way Merge sort is a variant of the Merge sort algorithm that considers 3 “equal” subarrays instead of 2 subarrays.

- (a) Given 3 sorted subarrays of size  $\frac{n}{3}$ , how many comparisons are needed (in the worst case) to merge them to a sorted array of size  $n$ ? Provide your answer in tilde notation.
- (b) What is the *order of growth* of the number of compares in 3-way Merge Sort as a function of the array size  $n$ ?
- (c) Given a choice, would you choose 3-way or 2-way merge sort? Justify your answer.

**OPTIONAL: Algorithm Design** (*Midterm Spring 2015*)

Let  $a = a_0, a_1, \dots, a_{n-1}$  be an array of length  $n$ . An array  $b$  is a circular shift of  $a$  if it consists of the subarray  $a_k, a_{k+1}, \dots, a_{n-1}$  followed by the subarray  $a_0, a_1, \dots, a_{k-1}$  for some integer  $k$ . In the example below,  $b$  is a circular shift of  $a$  (with  $k = 7$  and  $n = 10$ ).

**sorted array a[]**

1	2	3	5	6	8	9	34	55	89
---	---	---	---	---	---	---	----	----	----

**circular shift b[]**

34	55	89	1	2	3	5	6	8	9
----	----	----	---	---	---	---	---	---	---

Suppose that you are given an array  $b$  that is a circular shift of some sorted array (but you have access to neither  $k$  nor the sorted array). Assume that the array  $b$  consists of  $n$  comparable keys, no two of which are equal. Design an efficient algorithm to determine whether a given key appears in the array  $b$ . The order of growth of the running time of your algorithm should be  $\log n$  (or better) in the worst case, where  $n$  is the length of the array.

## ASSIGNMENT TIPS: Autocomplete

(1) Given an array of elements with duplicates, can we use the book implementation of Binary Search to find the **first occurrence** of an element?

- The standard implementation of Binary Search finds *an* occurrence, which is not necessarily the *first* occurrence.
- Finding the element and then scanning left to find the first occurrence yields a linear running time (in the worst case), which is not good!
- In this assignment, you will have to modify Binary Search to find the first (and last) occurrence of an element in a sorted array in logarithmic time (in the worst case).
- For full credit, your algorithm has to make at most  $1 + \lceil \log_2 n \rceil$  compares. However, if your algorithm has a logarithmic order of growth but makes more than  $1 + \lceil \log_2 n \rceil$  compares, you will lose *only* 1 point.

(2) What is the difference between a **Comparable** and a **Comparator**?

- A **Comparable**<T> is an object of a class that has the method **compareTo (T other)**. This method allows the object to compare itself to other objects.
- A **Comparator**<T> is an object that can be used to compare two given objects. It has the method **compare (T obj1, T obj2)**.
- Making an object **Comparable** makes it comparable with other objects using the logic provided in the **compareTo** method. However, if we want to implement multiple ways of comparison (for e.g. compare files by name, date created, date modified, etc.), then we need to have multiple Comparators.
- A good example of the use of **Comparable** and **Comparator** is **Point2D.java**, which is available at: <https://algs4.cs.princeton.edu/code/>. You can use this as a guide when working on the assignment.
- Note that a **Comparator** class can have a constructor that takes arguments. This may be needed in the assignment!

(3) What is the order of growth of the **substring** method?

- Creating a substring of length  $r$  takes time proportional to  $r$ .
- Note that the string comparison functions in the assignment should take time proportional to the number of characters needed to resolve the comparison.

**Example:** The comparison between  $X = \text{"AAAAAA"}$  and  $Y = \text{"AABBB"}$  can be resolved when the first "B" in Y is reached. The comparison function should *not* take time proportional to the size of X or the size of Y. It should take time proportional to the number of characters needed to resolve the comparison!

- Most uses of the **substring** method in the compare functions do not meet the above time constraint. So, be careful!

(4) A video that provides some tips for the assignment is available on the assignment Checklist page. The video was made in 2014, so a few things are outdated, but most of it still useful!
