GEOMETRIC APPLICATIONS OF BSTs

- ▶ *1d range search*
- ▶ *line segment intersection*
- ▶ *kd trees*
- ▶ *context*

Overview

This lecture. Intersections among **geometric objects**.

2d orthogonal range search

line segment intersection

Applications. CAD, games, movies, virtual reality, databases, GIS,

Efficient solutions. **Binary search trees** (and extensions).

Overview

This lecture. Only the tip of the iceberg.

<https://algs4.cs.princeton.edu>

GEOMETRIC APPLICATIONS OF BSTs

- ▶ *1d range search*
- ▶ *line segment intersection*
- ▶ *kd trees*

1d range search

Extension of ordered symbol table.

- Insert key–value pair.
- Search for key k .
- Delete key k .
- **Range search:** find all keys between k_1 and k_2 .
- **Range count:** number of keys between k_1 and k_2 .

Application. Database queries.

Geometric interpretation.

- Keys are point on a **line**.
- Find/count points in a given **1d interval**.

insert B	B
insert D	B D
insert A	A B D
insert I	A B D I
insert H	A B D H I
insert F	A B D F H I
insert P	A B D F H I P
search G to K	H I
count G to K	2

Suppose that the keys are stored in a sorted array of length n . What is the worst-case running time for **range search** as a function of both m and n ?

↖ number of matching keys

- A. $\Theta(\log m)$
- B. $\Theta(\log n)$
- C. $\Theta(\log n + m)$
- D. $\Theta(m + n)$

1d range search: elementary implementations

Unordered list. Slow insert; slow range search.

Sorted array. Slow insert; fast range search.

order of growth of running time for 1d range search

data structure	insert	range count	range search
unordered list	n	n	n
sorted array	n	$\log n$	$\log n + m$
goal	$\log n$	$\log n$	$\log n + m$

m = number of keys that match
 n = number of keys

1d range search: BST implementation

1d range search. Find all keys between k_1 and k_2 .

- Recursively find all keys in left subtree (if any could fall in range).
- Check key in current node.
- Recursively find all keys in right subtree (if any could fall in range).

range search [D...Q]

Proposition. Takes $\Theta(\log n + m)$ time in the worst case.

Pf. Nodes examined = { search path to k_1 } \cup { search path to k_2 } \cup { matches }.

1d range search: summary of performance

Unordered list. Slow insert; slow range search.

Sorted array. Slow insert; fast range search.

BST. Fast insert; fast range search/count.

order of growth of running time for 1d range search

data structure	insert	range count	range search
unordered list	n	n	n
sorted array	n	$\log n$	$\log n + m$
balanced BST	$\log n$	$\log n$	$\log n + m$

use rank() function
(see precept)

m = number of keys that match
 n = number of keys

GEOMETRIC APPLICATIONS OF BSTs

- ▶ *1d range search*
- ▶ *line segment intersection*
- ▶ *kd trees*
- ▶ *context*

Orthogonal line segment intersection

Given n horizontal and vertical line segments, find all intersections.

Quadratic algorithm. Check all pairs of line segments for intersection.

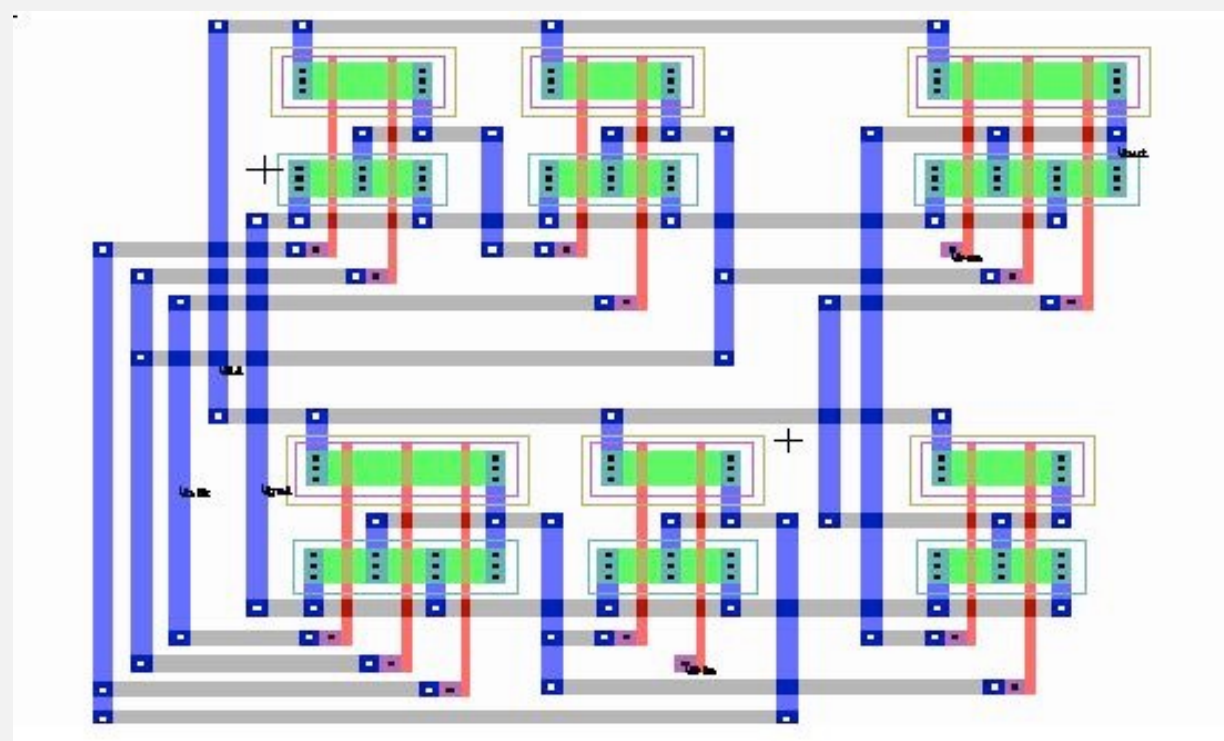

Microprocessors and geometry

Early 1970s. microprocessor design became a **geometric** problem.

- Very Large Scale Integration (VLSI).
- Computer-Aided Design (CAD).

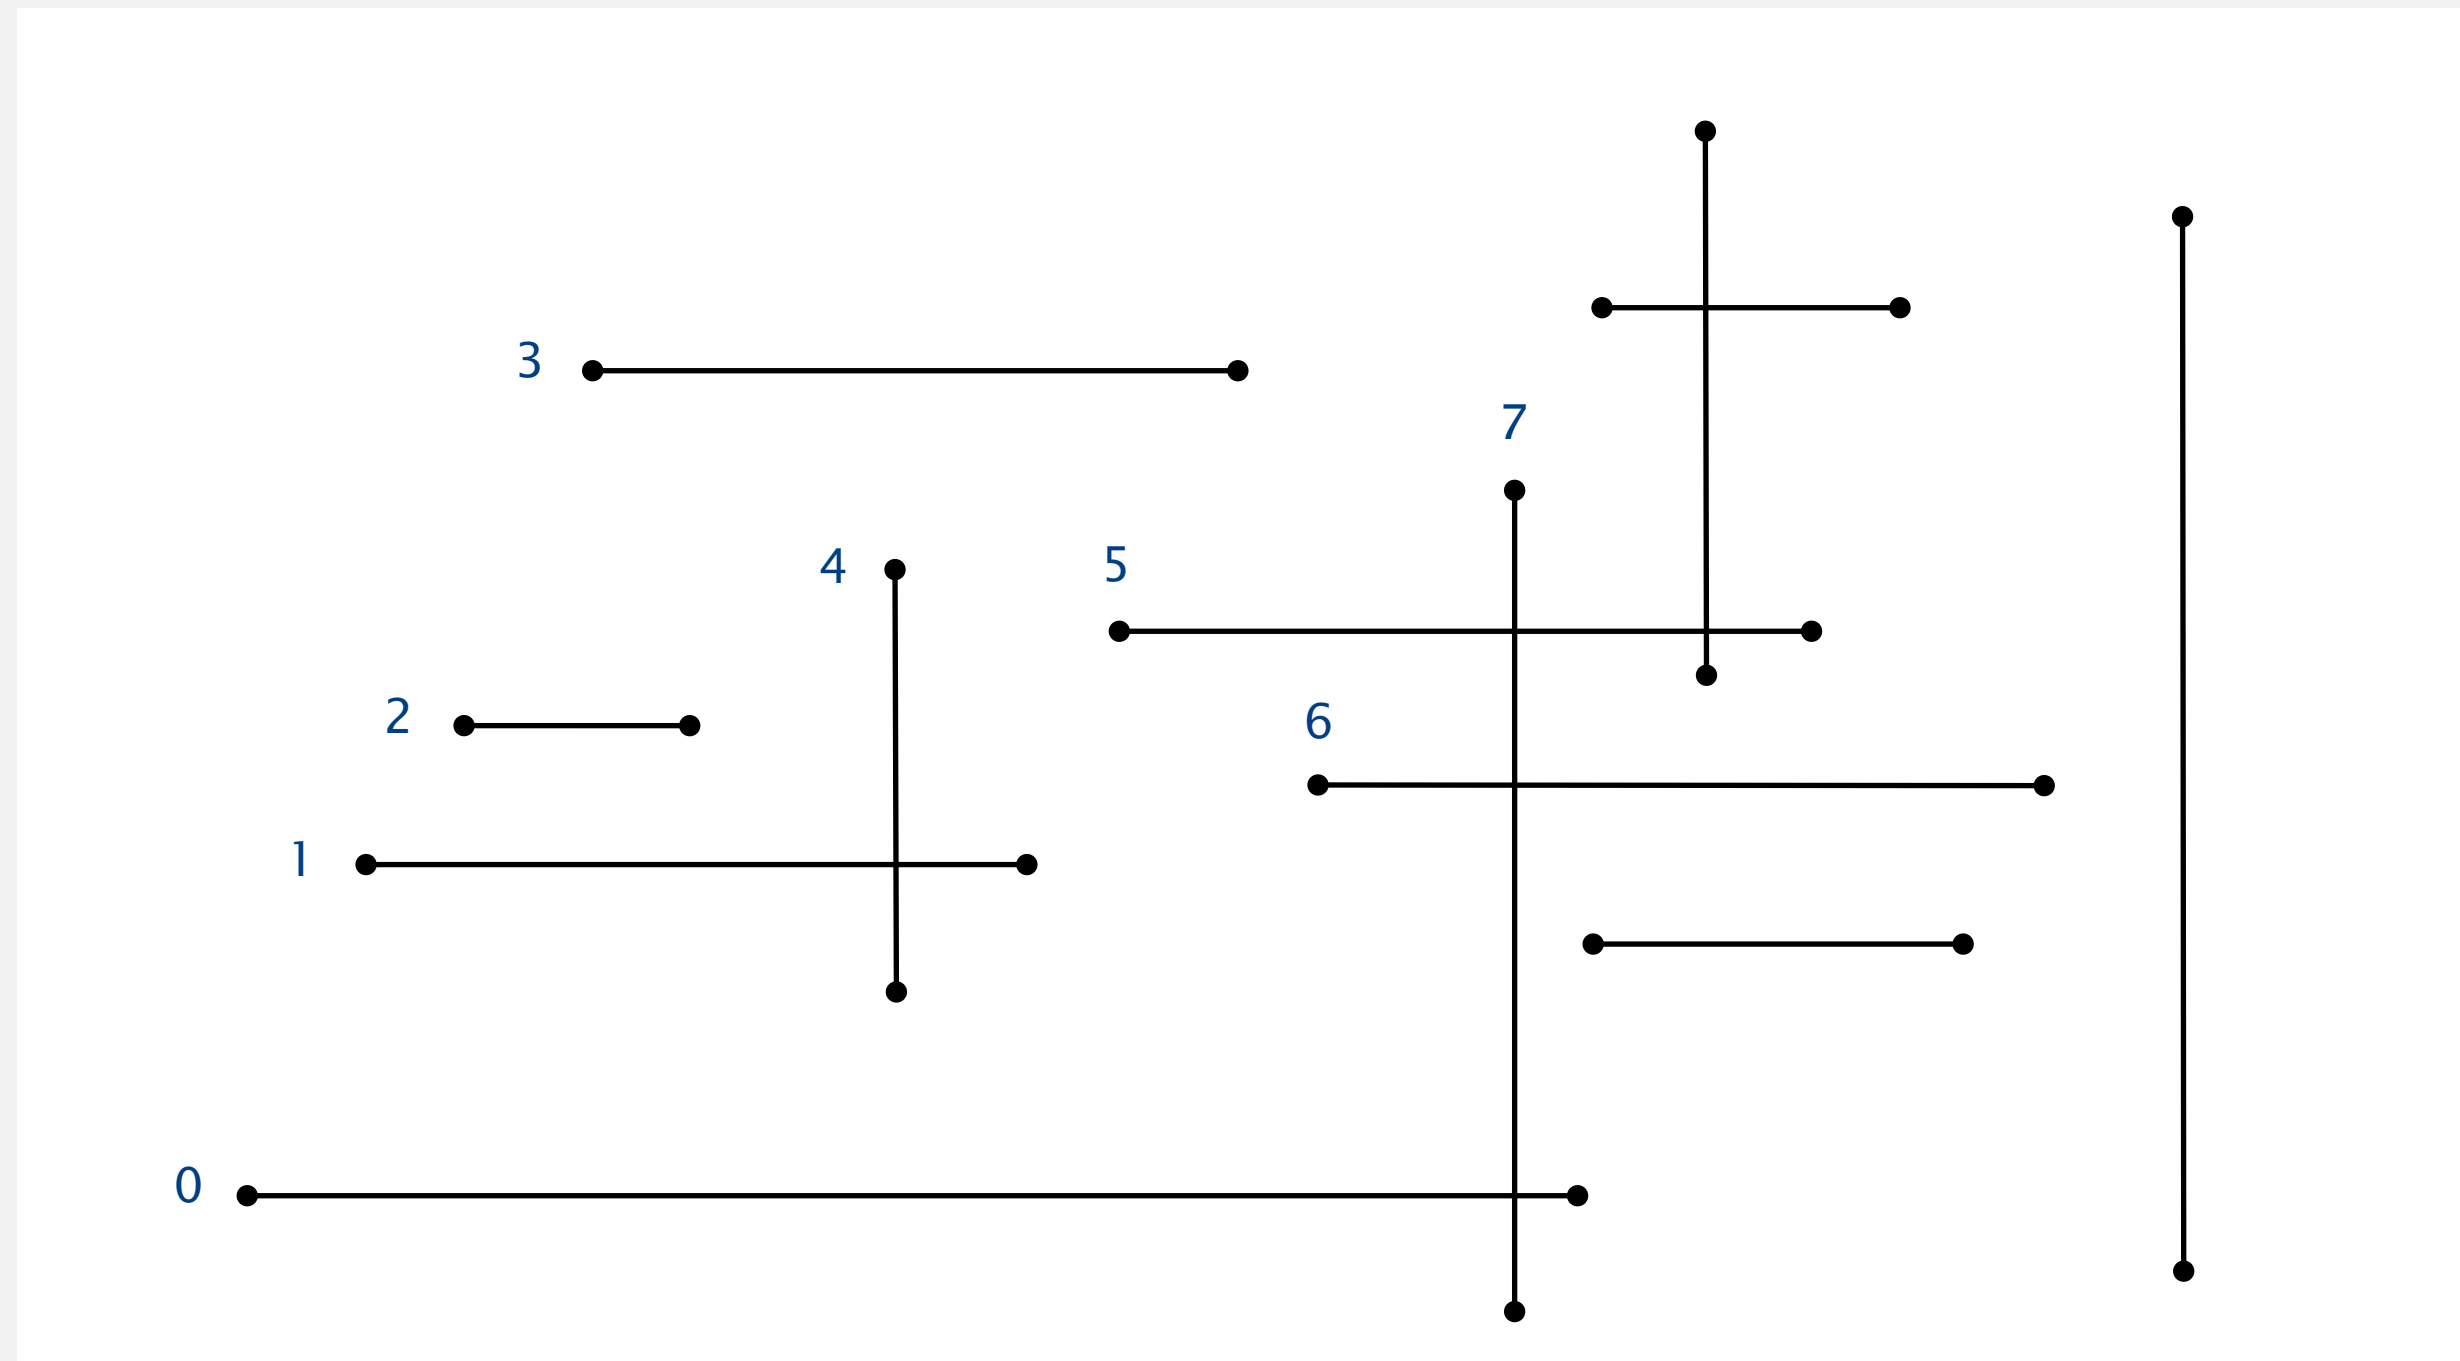

Design-rule checking.

- Certain wires cannot intersect.
- Certain spacing needed between different types of wires.
- Debugging = line segment (or rectangle) intersection.

Orthogonal line segment intersection: sweep-line algorithm

Non-degeneracy assumption. All x - and y -coordinates are distinct.

Orthogonal line segment intersection: sweep-line algorithm

Sweep vertical line from left to right. [x -coordinates define events]

- Horizontal segment (left endpoint): insert y -coordinate into BST.
- Horizontal segment (right endpoint): remove y -coordinate from BST.
- Vertical segment: range search for interval of y -endpoints.

y-coordinates
(of horizontal lines that intersect sweep line)

Orthogonal line segment intersection: sweep-line analysis

Proposition. The sweep-line algorithm takes $\Theta(n \log n + m)$ time in the worst case to find all m intersections among n horizontal and vertical line segments.

Pf.

- Sort x -coordinates. $[n \log n]$
 - Insert y -coordinates into BST. $[n \log n]$
 - Delete y -coordinates from BST. $[n \log n]$
 - Range searches in BST. $[n \log n + m]$
- \uparrow
 $(\log n + m_1) + (\log n + m_2) + (\log n + m_3) + \dots$

Bottom line. Sweep line reduces 2d orthogonal line segment intersection to 1d range search.

Sweep-line algorithm: context

The **sweep-line algorithm** is a key technique in computational geometry.

Geometric intersection.

- General line segment intersection.
- Axis-aligned rectangle intersection.
- ...

More problems.

- Andrew's algorithm for convex hull.
- Fortune's algorithm Voronoi diagram.
- Scanline algorithm for rendering computer graphics.
- ...

GEOMETRIC APPLICATIONS OF BSTs

- ▶ *1d range search*
- ▶ *line segment intersection*
- ▶ *kd trees*
- ▶ *context*

2-d orthogonal range search

Extension of ordered symbol-table to 2d keys.

- Insert a 2d key.
- Search for a 2d key.
- **Range search:** find all keys that lie in a 2d range.
- **Range count:** number of keys that lie in a 2d range.

Applications. Networking, circuit design, databases, ...

Geometric interpretation.

- Keys are point in the **plane**.
- Find/count points in a given ***h-v* rectangle**

↑
rectangle is axis-aligned

Space-partitioning trees

Use a **tree** to represent a recursive subdivision of 2d space.

Grid. Divide space uniformly into squares.

Quadtree. Recursively divide space into four quadrants.

2d tree. Recursively divide space into two halfplanes.

BSP tree. Recursively divide space into two regions.

Grid

Quadtree

2d tree

BSP tree

Space-partitioning trees: applications

Applications.

- Ray tracing.
- 2d range search.
- Flight simulators.
- N-body simulation.
- Collision detection.
- Astronomical databases.
- Nearest neighbor search.
- Adaptive mesh generation.
- Accelerate rendering in Doom.
- Hidden surface removal and shadow casting.

Grid

Quadtree

2d tree

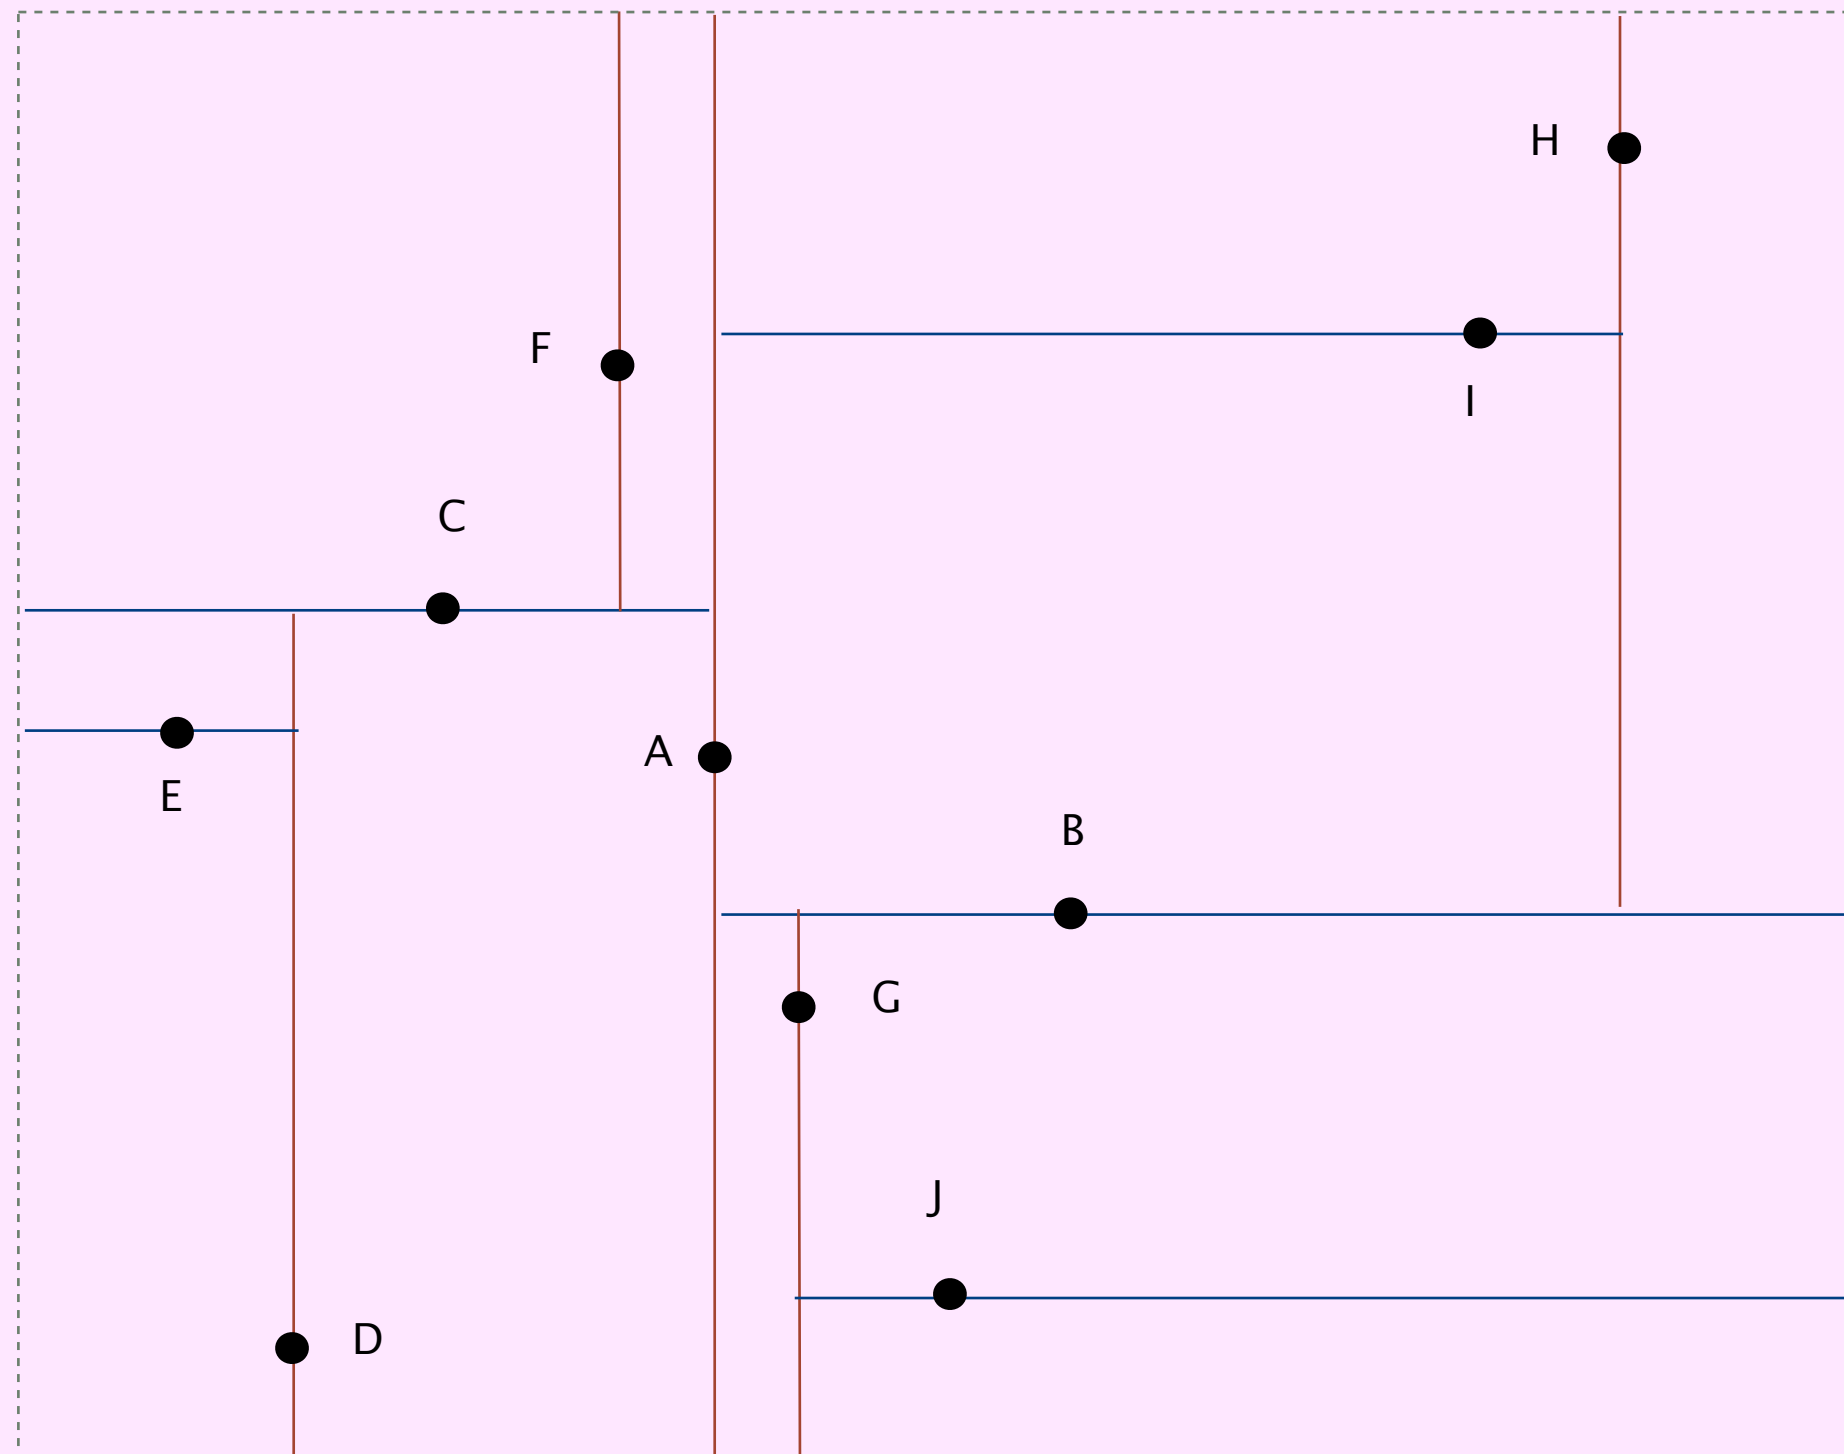

BSP tree

2d tree construction

Recursively partition plane into two halfplanes.

Where to insert point K in the 2d tree below?

- A. Left child of G.
- B. Left child of J.
- C. Right child of J.
- D. Right child of I.

2d tree implementation

Data structure. BST, but alternate using x - and y -coordinates as key.

- Each node corresponds to a rectangle containing point in node.
- Can store rectangle explicitly in node.

2d tree demo: range search

Goal. Find all points in a query rectangle.

- Check if query rectangle contains point in node.
- Recursively search left/bottom and right/top subtrees.
- Optimization: prune subtree if it can't contain a point in rectangle.

2d tree demo: range search

Goal. Find all points in a query rectangle.

- Check if query rectangle contains point in node.
- Recursively search left/bottom and right/top subtrees.
- Optimization: prune subtree if it can't contain a point in rectangle.

done

Suppose we explore the right/top subtree before the left/bottom subtree in range search. What effect would it have on typical inputs?

- A.** Returns wrong answer.
- B.** Explores more nodes.
- C.** Both A and B.
- D.** Neither A nor B.

Range search in a 2d tree analysis

Typical case. $\Theta(\log n + m)$.

Worst case (assuming tree is balanced). $\Theta(\sqrt{n} + m)$.

2d tree demo: nearest neighbor

Goal. Find closest point to query point.

2d tree demo: nearest neighbor

- Check distance from point in node to query point.
- Recursively search left/bottom and right/top subtrees.
- Optimization 1: prune subtree if it can't contain a closer point.
- Optimization 2: explore subtree toward the query point first.

nearest neighbor = E

Suppose we always explore the left/bottom subtree before the right/top subtree in nearest-neighbor search. What effect will it have on typical inputs?

- A.** Returns wrong answer.
- B.** Explores more nodes.
- C.** Both A and B.
- D.** Neither A nor B.

Which of the following is the worst case for nearest-neighbor search?

A.

B.

C.

D.

Nearest neighbor search in a 2d tree analysis

Typical case. $\Theta(\log n)$.

Worst case (even if tree is balanced). $\Theta(n)$.

nearest neighbor = E

2d tree: implementation

Q. How to implement a 2d-tree?

A. Explicit node data type for binary tree.

```
private class KdTreeST<Value>
{
    private Node root;

    private class Node
    {
        private Point2D p;
        private Value val;

        private Node left, right;
        private Node parent;

        private RectHV rect;

        ...
    }
    ...
}
```

very useful for 2D range search
and nearest neighbor search

GEOMETRIC APPLICATIONS OF BSTs

- ▶ *1d range search*
- ▶ *line segment intersection*
- ▶ *kd trees*
- ▶ ***context***

Kd tree

Kd tree. Recursively partition k -dimensional space into 2 halfspaces.

Implementation. BST, but cycle through dimensions à la 2d trees.

Efficient, simple data structure for processing k -dimensional data.

- Widely used.
- Adapts well to high-dimensional and clustered data.
- Discovered by an undergrad in an algorithms class!

- Q. Which “natural algorithm” do starlings, migrating geese, starlings, cranes, bait balls of fish, and flashing fireflies use to flock?

<https://www.youtube.com/watch?v=XH-groCeKbE>

Boids. Three simple rules lead to complex emergent flocking behavior:

- **Flock centering (cohesion):** move toward the center of mass of k nearest boids.
- **Direction matching (alignment):** update velocity toward average velocity of k nearest boids.
- **Collision avoidance (separation):** point away from k nearest boids.

N-body simulation

Goal. Simulate the motion of n particles, mutually affected by gravity.

Brute force. For each pair of particles, compute force: $F = \frac{G m_1 m_2}{r^2}$

Running time. Time per step is $\Theta(n^2)$.

https://www.youtube.com/watch?v=ua7YIN4eL_w

Appel's algorithm for n-body simulation

Key idea. Suppose that a particle is far, far away from a cluster of particles.

- Treat the cluster of particles as a single aggregate particle.
- Compute force between particle and **center of mass** of aggregate.

Appel's algorithm for n-body simulation

- Build 3d-tree with n particles as nodes.
- Store center-of-mass of subtree in each node.
- To compute total force acting on a particle, traverse tree, but stop as soon as distance from particle to subdivision is sufficiently large.

AN EFFICIENT PROGRAM FOR MANY-BODY SIMULATION*

ANDREW W. APPEL†

Abstract. The simulation of N particles interacting in a gravitational force field is useful in astrophysics, but such simulations become costly for large N . Representing the universe as a tree structure with the particles at the leaves and internal nodes labeled with the centers of mass of their descendants allows several simultaneous attacks on the computation time required by the problem. These approaches range from algorithmic changes (replacing an $O(N^2)$ algorithm with an algorithm whose time-complexity is believed to be $O(N \log N)$) to data structure modifications, code-tuning, and hardware modifications. The changes reduced the running time of a large problem ($N = 10,000$) by a factor of four hundred. This paper describes both the particular program and the methodology underlying such speedups.

Impact. Running time per step is $O(n \log n)$ \Rightarrow enables new research.
