

Introduction to Ocaml

Speaker: Andrew Appel COS 326 Princeton University

slides copyright 2020 David Walker and Andrew Appel permission granted to reuse these slides for non-commercial educational purposes

Why OCaml?

Small, orthogonal core based on the *lambda calculus*.

- Control is based on (recursive) functions.
- Instead of for-loops, while-loops, do-loops, iterators, etc.
 - can be defined as library functions.
- Makes it easy to define semantics

Supports *first-class, lexically scoped, higher-order* procedures

- a.k.a. first-class functions or closures or lambdas.
- first-class: functions are data values like any other data value
 - like numbers, they can be stored, defined anonymously, ...
- lexically scoped: meaning of variables determined statically.
- higher-order: functions as arguments and results
 - programs passed to programs; generated from programs

These features also found in Scheme, Haskell, Scala, F#, Clojure,

Why OCaml?

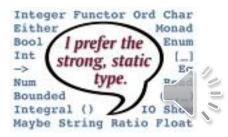

Statically typed: debugging and testing aid

- compiler catches many silly errors before you can run the code.
 - A type is worth a thousand tests
- Java is also strongly, statically typed.
- Scheme, Python, Javascript, etc. are all strongly, *dynamically typed* – type errors are discovered while the code is running.

Strongly typed: compiler enforces type abstraction.

- cannot cast an integer to a record, function, string, etc.
 - so we can utilize *types as capabilities*; crucial for local reasoning
- C/C++ are weakly typed (statically typed) languages. The compiler will happily let you do something smart (more often stupid).

Type inference: compiler fills in types for you

Installing, Running OCaml

- OCaml comes with compilers:
 - "ocamlc" fast bytecode compiler
 - "ocamlopt" optimizing, native code compiler
 - "ocamlbuild a nice wrapper that computes dependencies
- And an interactive, top-level shell:
 - useful for trying something out.
 - "ocaml" at the prompt.
 - but use the compiler most of the time
- And many other tools
 - e.g., debugger, dependency generator, profiler, etc.
- See the course web pages for installation pointers
 - also OCaml.org

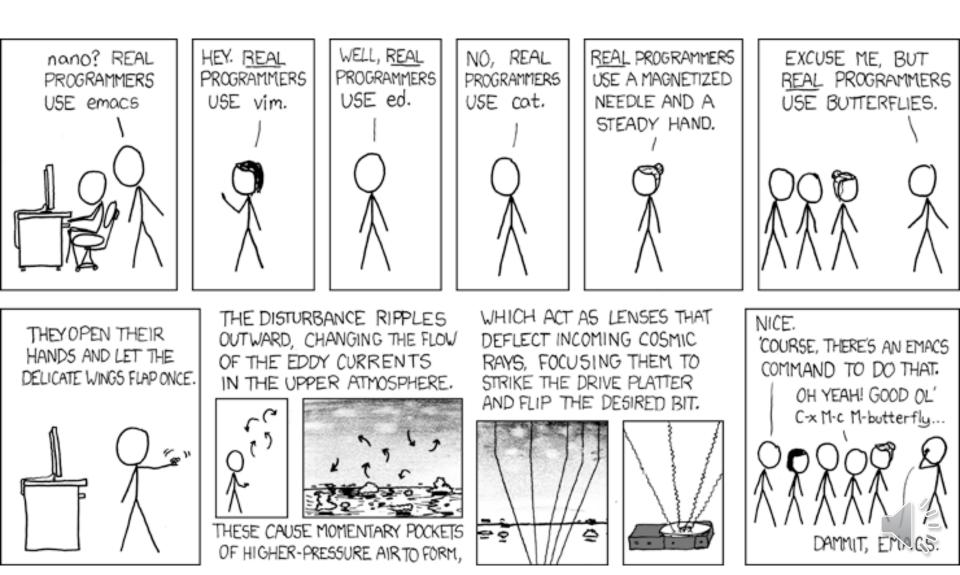

Editing OCaml Programs

- Many options: pick your own poison
 - Emacs
 - what your professors use
 - good but not great support for OCaml.
 - we like it because we're used to it
 - (extensions written in elisp a functional language!)
 - OCaml IDE
 - integrated development environment written in OCaml.
 - haven't used it, so can't comment.
 - Eclipse
 - we've put up a link to an OCaml plugin
 - we haven't tried it but others recommend it
 - Sublime, atom
 - A lot of students seem to gravitate to this

OCAML BASICS: EXPRESSIONS, VALUES, SIMPLE TYPES

Terminology: Expressions, Values, Types

Expressions are computations

- 2 + 3 is a computation

Values (a subset of the expressions) are the results of computations

- 5 is a value

Types describe collections of values and the computations that generate those values

- int is a type
- values of type int include
 - 0, 1, 2, 3, ..., max_int
 - -1, -2, ..., min_int

Some simple types, values, expressions

<u>Type</u> :	<u>Values</u> :	Expressions:
int	-2, 0, 42	42 * (13 + 1)
float	3.14, -1., 2e12	(3.14 +. 12.0) *. 10e6
char	'a', 'b', '&'	int_of_char 'a'
string	"moo", "cow"	"moo" ^ "cow"
bool	true, false	if true then 3 else 4
unit	()	print_int 3

For more primitive types and functions over them, see the OCaml Reference Manual here:

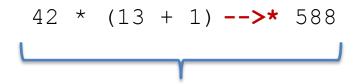

http://caml.inria.fr/pub/docs/manual-ocaml/libref/Pervasives.html

42 * (13 + 1)

42

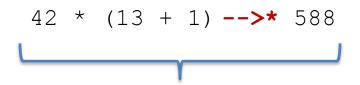

Read like this: "the expression 42 * (13 + 1) evaluates to the value 588"

The "*" is there to say that it does so in 0 or more small steps

43

Read like this: "the expression 42 * (13 + 1) evaluates to the value 588"

The "*" is there to say that it does so in 0 or more small steps

Here I'm telling you how to execute an OCaml expression --- ie, I'm telling you something about the *operational semantics* of OCaml

More on semantics later.

42 * (13 + 1) -->* 588

(3.14 +. 12.0) *. 10e6 -->* 151400000.

int of char 'a' -->* 97

"moo" ^ "cow" -->* "moocow"

if true then 3 else 4 ->* 3

print int 3 -->* ()

1 + "hello" -->* ???

46

1 + "hello" -->* ???

"+" processes integers "hello" is not an integer evaluation is undefined!

Don't worry! This expression doesn't type check.

Aside: See this talk on Javascript: https://www.destroyallsoftware.com/talks/wat

-47

OCAML BASICS: CORE EXPRESSION SYNTAX

Core Expression Syntax

The simplest OCaml expressions e are:

- values
- id
- e₁ op e₂
- id e₁ e₂ ... e_n
- let id = e_1 in e_2
- if e_1 then e_2 else e_3
- (e)
- (e:t)

numbers, strings, bools, ... variables (x, foo, ...) operators (x+3, ...) function call (foo 3 42) local variable decl. a conditional a parenthesized expression an expression with its type

A note on parentheses

In most languages, arguments are parenthesized & separated by commas:

f(x, y, z) sum (3, 4, 5)

In OCaml, we don't write the parentheses or the commas:

fxyz sum 345

But we do have to worry about grouping. For example,

```
f x y z same as: ((f x) y) z
not the same as: f x (y z)
```

The first one passes three arguments to f (x, y, and z) The second passes two arguments to f (x, and the result of applying the function y to z.)

OCAML BASICS: TYPE CHECKING

Every value has a type and so does every expression

This is a concept that is familiar from Java but it becomes more important when programming in a functional language

We write (e : t) to say that *expression* e *has type* t. eg:

2 : int

"hello" : string

2 + 2 : int

"I say " ^ "hello" : string

There are a set of simple rules that govern type checking

- programs that do not follow the rules will not type check and O'Caml will refuse to compile them for you (the nerve!)
- at first you may find this to be a pain ...

But types are a great thing:

- help us *think* about *how to construct* our programs
- help us *find stupid programming errors*
- help us track down errors quickly when we edit our code
- allow us to enforce powerful invariants about data structures

Example rules:

- (1) **0**: int (and similarly for any other integer constant n)
- (2) "abc": string (and similarly for any other string constant "...")

Example rules:

- (1) **0**: int (and similarly for any other integer constant n)
- (2) "abc": string (and similarly for any other string constant "...")
- (3) if e1 : int and e2 : int
 (4) if e1 : int and e2 : int
 then e1 + e2 : int
 then e1 * e2 : int

Example rules:

- (1) **0**: int (and similarly for any other integer constant n)
- (2) "abc": string (and similarly for any other string constant "...")
- (3) if e1 : int and e2 : int then e1 + e2 : int
- (5) if e1 : string and e2 : string then e1 ^ e2 : string
- (4) if e1 : int and e2 : int then e1 * e2 : int
- (6) if e : int then string_of_int e : string

Example rules:

- (1) **0**: int (and similarly for any other integer constant n)
- (2) "abc": string (and similarly for any other string constant "...")
- (3) if e1 : int and e2 : int then e1 + e2 : int
- (5) if e1 : string and e2 : string then e1 ^ e2 : string

- (4) if e1 : int and e2 : int then e1 * e2 : int
- (6) if e : int then string_of_int e : string

Using the rules:

2: int and 3: int. (By rule 1)

Example rules:

- (1) **0**: int (and similarly for any other integer constant n)
- (2) "abc": string (and similarly for any other string constant "...")
- (3) if e1 : int and e2 : int then e1 + e2 : int
- (5) if e1 : string and e2 : string then e1 ^ e2 : string

- (4) if e1 : int and e2 : int then e1 * e2 : int
- (6) if e : int then string_of_int e : string

Using the rules:

2 : int and 3 : int. (By rule 1) Therefore, (2 + 3) : int (By rule 3)

Example rules:

- (1) **0**: int (and similarly for any other integer constant n)
- (2) "abc": string (and similarly for any other string constant "...")
- (3) if e1 : int and e2 : int then e1 + e2 : int
- (5) if e1 : string and e2 : string then e1 ^ e2 : string

- (4) if e1 : int and e2 : int then e1 * e2 : int
- (6) if e : int then string_of_int e : string

Using the rules:

 2 : int and 3 : int.
 (By rule 1)

 Therefore, (2 + 3) : int
 (By rule 3)

 5 : int
 (By rule 1)

Example rules:

- (1) **0**: int (and similarly for any other integer constant n)
- (2) "abc" : string (and similarly for
- (3) if e1 : int and e2 : int then e1 + e2 : int
- (5) if e1 : string and e2 : string then e1 ^ e2 : string

FYI: This is a *formal proof* that the expression is welltyped!

rmg_or_int e : string

Using the rules:

- 2 : int and 3 : int. Therefore, (2 + 3) : int 5 : int
- (By rule 1) (By rule 3) (By rule 1)

Therefore, (2 + 3) * 5 : int (By rule 4 and our previous work)

Example rules:

- (1) **0**: int (and similarly for any other integer constant n)
- (2) "abc": string (and similarly for any other string constant "...")
- (3) if e1 : int and e2 : int then e1 + e2 : int
- (5) if e1 : string and e2 : string then e1 ^ e2 : string
- Another perspective:

(4) if e1 : int and e2 : int then e1 * e2 : int

(6) if e : int then string_of_int e : string

rule (4) for typing expressions says I can put any expression with type int in place of the ????

Example rules:

- (1) **0**: int (and similarly for any other integer constant n)
- (2) "abc": string (and similarly for any other string constant "...")
- (3) if e1 : int and e2 : int then e1 + e2 : int
- (5) if e1 : string and e2 : string then e1 ^ e2 : string
- Another perspective:

- (4) if e1 : int and e2 : int then e1 * e2 : int
- (6) if e : int then string_of_int e : string

rule (4) for typing expressions says I can put any expression with type int in place of the ????

7

Example rules:

- (1) **0**: int (and similarly for any other integer constant n)
- (2) "abc": string (and similarly for any other string constant "...")
- (3) if e1 : int and e2 : int then e1 + e2 : int
- (5) if e1 : string and e2 : string then e1 ^ e2 : string
- Another perspective:

- (4) if e1 : int and e2 : int then e1 * e2 : int
- (6) if e : int then string_of_int e : string

(add one 17) : int

rule (4) for typing expressions says I can put any expression with type int in place of the ????

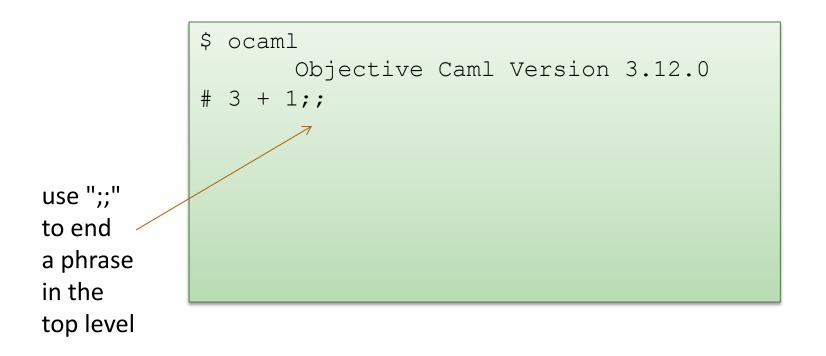

You can always start up the OCaml interpreter to find out a type of a simple expression:

- (1) **0**: int (and similarly for any other integer constant n)
- (2) "abc": string (and similarly for any other string constant "...")
- (3) if e1 : int and e2 : int then e1 + e2 : int
- (5) if e1 : string and e2 : string then e1 ^ e2 : string

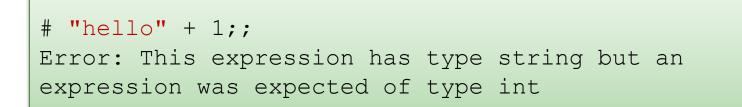

- (4) if e1 : int and e2 : int then e1 * e2 : int
- (6) if e : int then string_of_int e : string

Violating the rules:

"hello" : string 1 : int 1 + "hello" : ?? (By rule 2)
(By rule 1)
(NO TYPE! Rule 3 does not apply!)

Violating the rules:

The type error message tells you the type that was expected and the type that it inferred for your subexpression

By the way, this was one of the nonsensical expressions that did not evaluate to a value

It is a *good thing* that this expression does not type check!

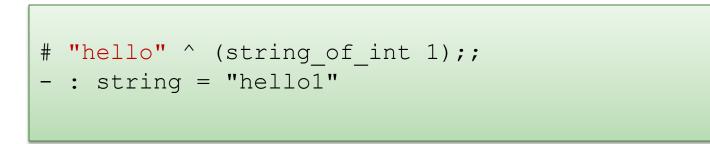

"Well typed programs do not go wrong" Robin Milner, 1978

Violating the rules:

```
# "hello" + 1;;
Error: This expression has type string but an
expression was expected of type int
```

A possible fix:

One of the keys to becoming a good ML programmer is to understand type error messages.

What about this expression:

```
# 3 / 0 ;;
Exception: Division_by_zero.
```

Why doesn't the ML type checker do us the favor of telling us the expression will raise an exception?

What about this expression:

```
# 3 / 0 ;;
Exception: Division_by_zero.
```

Why doesn't the ML type checker do us the favor of telling us the expression will raise an exception?

- In general, detecting a divide-by-zero error requires we know that the divisor evaluates to 0.
- In general, deciding whether the divisor evaluates to 0 requires solving the halting problem:

```
# 3 / (run turing machine(); 0);;
```

There are type systems that will rule out divide-by-zero errors, but they require programmers supply proofs to the type checker

"Well typed programs do not go wrong" Robin Milner, 1978

(3 / 0) is well typed. Does it "go wrong?" Answer: No.

"Go wrong" is a technical term meaning, "have no defined semantics." Raising an exception is perfectly well defined semantics, which we can reason about, which we can handle in ML with an exception handler.

So, it's not cheating.

(Discussion: why do we make this distinction, anyway?)

"Well typed programs do not go wrong"

Programming languages with this property have sound type systems. They are called *safe* languages.

Safe languages are generally *immune* to buffer overrun vulnerabilities, uninitialized pointer vulnerabilities, etc., etc. (but not immune to all bugs!)

Safe languages: ML, Java, Python, ...

Unsafe languages: C, C++, Pascal

OVERALL SUMMARY: A SHORT INTRODUCTION TO FUNCTIONAL PROGRAMMING

OCaml is a *functional* programming language

express control flow and iteration by defining *functions*

OCaml is a *typed* programming language

- the type of an expression correctly predicts the kind of value the expression will generate when it is executed
- types help us *understand* and *write* our programs
- the type system is *sound*; the language is *safe*
