

Spanner

(Part II)

COS 418: Distributed Systems
Lecture 18

Mike Freedman, Jialin Ding

Some slides from the Spanner OSDI talk

1

Recap: Spanner is Strictly Serializable

- Efficient read-only transactions in strictly serializable systems
 - Strict serializability is desirable but costly!
 - Reads are prevalent! (340x more than write txns)
 - Efficient rotxns → good system overall performance

2

Recap: Ideas Behind Read-Only Txns

- Tag writes with physical timestamps upon commit
 - Write txns are strictly serializable, e.g., 2PL
- Read-only txns return the writes, whose commit timestamps precede the reads' current time
 - Rotxns are one-round, lock-free, and never abort

3

Recap: TrueTime

- Timestamping writes must enforce the invariant
 - If T2 starts after T1 commits (finishes), then T2 must have a larger timestamp
- TrueTime: partially-synchronized clock abstraction
 - Bounded clock skew (uncertainty)
 - $TT.now() \rightarrow [earliest, latest]; earliest \leq T_{abs} \leq latest$
 - Uncertainty (ϵ) is kept short
- TrueTime enforces the invariant by
 - Use at least $TT.now().latest$ for timestamps
 - Commit wait

4

Enforcing the Invariant with TT

If T2 starts after T1 commits (finishes), then T2 must have a larger timestamp

Let T1 write S_B and T2 write S_A

5

Enforcing the Invariant with TT

If T2 starts after T1 commits (finishes), then T2 must have a larger timestamp

Let T1 write S_B and T2 write S_A

6

Enforcing the Invariant with TT

- What if T1.commit delayed, such that T2 happens after T1.now() but before T1.commit.ts = T1.now().latest
- Answer: T2 delayed until after T1 commits. Discussed later.

7

This Lecture

- How write transactions are done
 - 2PL + 2PC (sometimes 2PL for short)
 - How they are timestamped
- How read-only transactions are done
 - How read timestamps are chosen
 - How reads are executed

8

Read-Write Transactions (2PL)

- Three phases

9

Read-Write Transactions (2PL)

Txn T = {R(A=?), W(A=?+1), W(B=?+1), W(C=?+1)}

Execute:

- Does reads: grab read locks and return the most recent data, e.g., R(A=a)
- Client computes and buffers writes locally, e.g., A = a+1, B = a+1, C = a+1

10

Read-Write Transactions (2PL)

Prepare:

- Choose a coordinator, e.g., A, others are participants
- Send buffered writes and the identity of the coordinator; grab write locks
- Each participant prepares T by logging a prepare record via Paxos with its replicas. Coord skips prepare (Paxos Logging)
- Participants send OK to coord if lock grabbed and after Paxos logging is done

11

Read-Write Transactions (2PL)

Commit:

- After hearing from all participants, coord commits T if all OK; o/w, abort T
- Coord logs commit/abort record via Paxos, applies writes if commit, release locks
- Coord sends commit/abort messages to participants
- Participants log commit/abort via Paxos, apply writes if commit, release locks
- Coord sends result to client either after its "log commit" or after ack

12

Timestamping Read-Write Transactions

13

13

Read-Only Transactions (shards part)

14

14

Read-Only Transactions (Paxos part)

15

15

Read-Only Transactions (Paxos part)

16

16

Serializable Snapshot Reads

- Client specifies a read timestamp way in the past
 - E.g., one hour ago
- Read shards at the stale timestamp
- Serializable
 - Old timestamp cannot ensure real-time order
- Better *performance*
 - No waiting in any cases
 - E.g., non-blocking, not just lock-free
- Can have performance but still strictly serializable?
 - E.g., one-round, non-blocking, and strictly serializable
 - Coming in next lecture!

19

19

Takeaway

- Strictly serializable (externally consistent)
 - Make it easy for developers to build apps!
- Reads dominant, make them efficient
 - One-round, lock-free
- TrueTime exposes clock uncertainty
 - Commit wait and at least `TT.now.latest()` for timestamps ensure real-time ordering
- Globally-distributed database
 - 2PL w/ 2PC over Paxos!
