Programming Style

- Writing good programs is like writing good prose; the object is to *communicate* concise, straightforward, no unnecessary parts
- Principles of good programming style are <u>language independent</u> some languages have features that <u>encourage</u> good style, e.g. structured loops some have features that <u>discourage</u> good style, e.g. gotos, anemic data types modern block-structured languages are better than older unstructured languages but **bad** programs can be written in **any** language
- Benefits of good style code that is easy to <u>understand</u> code that is more likely to <u>work</u> code that is easy to <u>maintain</u> and change
- Method to develop good programming style
 <u>read</u> code written by good programmers
 Ask: Will I understand this program in two years?

Names

- Pick names that capture the use of the variable or function, e.g. addElement
 - nouns for variables verbs for functions adjectives for booleans, conditions, and some enumeration constants
- Use *descriptive* names for global variables and functions, e.g. elementCount
- Use <u>concise</u> names for local variables that reflect <u>standard notation</u>

• Use *<u>case</u>* judiciously

use all capitals for constants don't rely on only case to distinguish names

- Use a consistent style for <u>compound</u> names printword PrintWord print_word
- Module-level prefixes help distinguish names, e.g. strset_T, strset_add
- Don't use nerdy abbreviations and acronyms

Use <u>white space</u> judiciously

separate code into "paragraphs"

make expressions more readable

• Use *indentation* to emphasize *structure*

use editor "autoindent" facilities and a consistent amount of space

watch for extreme indentation - signals excessive nesting

Line up parallel structures

	alpha	=	angle(p1,	p2,	p3);
<pre>beta = angle(p2, p3, p1);</pre>	beta	=	angle(p2,	p3,	p1);
gamma = angle(p3, p1, p2);	gamma	=	angle(p3,	pl,	p2)

- One statement per line
- Be *consistent*, but use *variation* for emphasis
- Break long lines at logical places, e.g. by precedence; indent continuations
- Use tabular input and output formats

```

Computer Science 217: Style

Page 108

October 1, 1999

Clear Expression

• Compare:

```
for(i=1; i<=n; i++)
for(j=1; j<=n; i++)
v[i-1][j-1] = (i/j)*(j/i);
VS.
/* make v the identity matrix */
for (i = 0; i < n; i++) {
   for (j = 0; j < n; j++)
       v[i][j] = 0.0;
   v[i][i] = 1.0;
}</pre>
```

• Rules:

be clever, but don't be too clever

say what you mean, simply and directly

use parentheses to emphasize precedence and braces to display structure

- use white space and indentation to clarify structure
- don't sacrifice clarity for "efficiency"

Clear Expression, cont'd

• Compare:

```
if (!(i > 10 || 0 > i)) ... VS. if (0 <= i && i <= 10) ...
• Compare:
    for (neg = 0; *s1 == *s2++; )
        if (*s1++ == '\0')
            break;
    neg = *s1 - (*--s2);
    if (!neg) ...
    VS.
    while (*s1 == *s2 && *s1 != '\0') { s1++; s2++; }
    if (*s1 == *s2) ...
    VS.
    if (strcmp(s1, s2) == 0) ...</pre>
```

• Rules:

avoid double negation avoid temporary variables use library functions let the compiler do the dirty work

Copyright ©1997

Computer Science 217: Style

Page 110

October 1, 1999

Clear Expression, cont'd

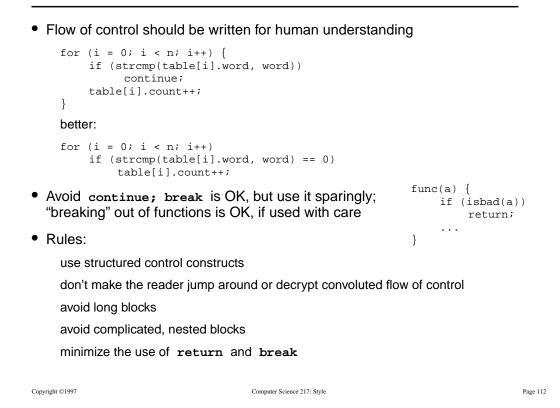

• Compare:

```
if (a > b)
                     vs.
                                if (a < b)
    if (b > c)
                                    if (b <= c)
        z = c;
                                        z = a;
                                     else
    else
                                        z = c;
        z = b;
                                        /* a >= b *
                                else
else
                                    if (b <= c)
    if (a > c)
                                        z = b
        z = c;
                                     else
    else
                                         z = c;
        z = a;
better yet:
z = min(a, min(b, c));
```

• Rules:

lay out expressions according to standard conventions rearrange logic so it is easy to understand follow each decision with a matching action

Control Structure

October 1, 1999

Control Structure, cont'd

• "Comb" structures

compare:

```
if (x < v[mid])
    high = mid - 1;
else if (x > v[mid])
    low = mid + 1;
else
    return mid;
```

```
VS:
if (x < v[mid])
    high = mid - 1;
    else if (x > v[mid])
        low = mid + 1;
        else
        return mid;
```

- Ditto for switch
- Rules:

implement multiway branches with if ... else if ... else emphasize that only one of the actions is performed avoid empty then and else actions handle default action, even if it "can't happen;" use assert(0) avoid nesting

Program Structure

• Rules:

modularize; use interfaces every function/interface should do <u>one</u> thing well every function/interface should <u>hide</u> something replace repetitious code with calls to functions let the data structure the program make sure your code "does nothing" gracefully don't patch bad code — rewrite it don't strain to reuse code — reorganize it watch for "off-by-one" errors

Documentation

- Best program documentation includes
 - clean structure
 - consistent programming
 - good mnemonic identifiers
 - smattering of enlighting comments
- · Comments should add new information

```
i = i + 1; /* add one to i */
```

- · Comments and code must *agree*; if they disagree, odds are they are both wrong
- Don't comment bad code rewrite it
- Comment algorithms, not coding idiosyncracies
- Comment procedural interfaces and data structures liberally
- Master the language and its *idioms*; let the code speak for itself

Program Organization

- · Good, consistent organization makes programs easier to read and modify
- Pick a consistent program layout style for
 - functions statements expressions comments
- <u>Small</u> programs (~ few <u>hundred</u> lines, maximum) can fit into one file

```
opening explanatory comments
purpose
author and history (handled better by tools like RCS)
#includes (i.e. imports)
#defines (i.e. constants)
type definitions (e.g. typedef, struct, etc.)
global variables
main
functions in alphabetical or logical order
```

Maximize "data ink"

Computer Science 217: Style

Page 116

October 1, 1999

Program Organization, cont'd

- Divide medium-size programs (~ few *thousand* lines, maximum) into modules
- · Use established interfaces and implementations
- Implementations
 - organized around data or function
 - organize each implementation as a "small" program
- Interfaces
 - use separate headers for separate interfaces, but don't over-modularize
 - permit multiple inclusion
 - do <u>not</u> define variables
- Global variables and functions
 - <u>declared</u> in interfaces, so all clients see the same declaration <u>defined</u> and <u>initialized</u> in an implementation
- What about *large* programs, say, more than 50,000 lines? Another course...

Efficiency and Style

- If a program doesn't work, it doesn't matter how fast it is!
- Rules:

make it clear before you make it faster

make it correct before you make it faster

see if it's fast enough before you make it faster

keep it correct while you make it faster

ill-conceived attempts to increase efficiency usually lead to bad code; gains are usually small or non-existent

Make performance improvements <u>only</u>

if they are really needed, and

if there are objective *measurements* that identify the sources of inefficiency intuitions are notoriously bad; they aren't "objective measurements"

• Rules:

keep it simple to make it faster let the compiler do the simple optimizations don't diddle code to make it faster — find a better algorithm
