

## Arithmetic Operators

---

- “Normal” binary arithmetic operators: + - \* /
- Modulus or remainder operator: %
  - $x\%y$  is the remainder when  $x$  is divided by  $y$
  - well defined **only** when  $x > 0$  and  $y > 0$
- Unary operators: - +
- Precedence (see H&S, section 7.2.1)
  - highest      unary - +
  - \* / %
  - lowest        + -
  - so  $-2*a + b$  is parsed as  $((-2)*a) + b$
- Associativity: left to right
  - $a + b + c$  is parsed as  $((a + b) + c)$

## Portability: Printing Numbers

---

- Print a number in decimal
 

```
void putd(int n) {
    if (n < 0) {
        putchar('-');
        n = -n;
    }
    if (n >= 10)
        putd(n/10);
    putchar(n%10 + '0');
}
```
- Can this program print `INT_MIN == -2147483648?`

## Portability: Printing Numbers, Cont'd

- Convert to negative numbers

```
static void putneg(int n) {
    if (n <= -10)
        putneg(n/10);
    putchar("0123456789"[-(n%10)]);
}

void putd(int n) {
    if (n < 0) {
        putchar('-');
        putneg(n);
    } else
        putneg(-n);
}
```

- $n/10$  and  $n\%10$  are "implementation dependent" when  $n < 0$

## Portability, cont'd

- Remainder is a mess:

```
int a, b, q, r;
q = a/b; r = a%b;
ANSI Standard guarantees only
q*b + r == a
|r| < |b|
r >= 0 when a >= 0 && b > 0
r might be negative if a is
```

$$5/(-3) = -1.666\dots$$

$$\begin{aligned} \text{if } 5/(-3) == -2, \\ 5\%(-3) &= 5 - (-2)(-3) = -1 \\ \text{if } 5/(-3) == -1, \\ 5\%(-3) &= 5 - (-1)(-3) = 2 \end{aligned}$$

- Check for sign of  $n\%10$ , handle both

```
static void putneg(int n) {
    int q = n/10, r = n%10;
    if (r > 0) {
        r -= 10;
        q++;
    }
    if (n <= -10)
        putneg(q);
    putchar("0123456789"[-r]);
}
```

$$\begin{aligned} \text{if } (-7)/10 == -1, \\ (-7)\%10 &= -7 - (-1)(10) = 3 \\ \text{if } (-7)/10 == 0, \\ (-7)\%10 &= -7 - (0)(10) = -7 \end{aligned}$$

## An Easier Way

---

- Use unsigned arithmetic

```
#include <limits.h>
#include <stdio.h>

static void putu(unsigned n) {
    if (n > 10)
        putu(n/10);
    putchar("0123456789"[n%10]);
}

void putd(int n) {
    if (n == INT_MIN) {
        putchar('-');
        putu((unsigned)INT_MAX + 1);
    } else if (n < 0) {
        putchar('-');
        putu(-n);
    } else
        putu(n);
}
```

## Increment/Decrement

---

- **Prefix** operator increments operand **before** returning the value

```
n = 5;
x = ++n;
```

**x** is 6, **n** is 6

- **Postfix** operator increments operand **after** returning the value

```
n = 5;
x = n++;
```

**x** is 5, **n** is 6

- Operands of ++ and -- must be **variables**

```
++1
2 + 3++
```

are illegal

## Relational & Logical Operators

---

- Logical values are `ints`: 0 is false, !0 is true
- “Normal” relational operators: `> >= < <=`
- Equality operators: `== !=`
- Unary logical negation: `!`
- Logical connectives: `&& ||`

Evaluation rules: left-to-right ; **as far as** to determine outcome

`&&` stops when the outcome is known to be 0

`||` stops when the outcome is known to be !0

```
if (i >= 0 && i < 10 && a[i] == max)
    ++a[i];
```

- Associativity: left to right; precedence:

highest	!
	arithmetic operators
	< <= >= >
	== !=
	&&
lowest	

## Bit Manipulation

---

- Bitwise logical operators apply to all the bits of an integer value:

<code>&amp;</code>	bitwise AND	<code>1&amp;1=1</code>	<code>0&amp;1=0</code>
<code> </code>	bitwise inclusive OR	<code>1 0=1</code>	<code>0 0=0</code>
<code>^</code>	bitwise exclusive OR	<code>1^1=0</code>	<code>1^0=1</code>
unary <code>~</code>	bitwise complement	<code>~1=0</code>	<code>~0=1</code>

- The `|` operator can be used to “turn on” one or more bits

```
#define BIT0 0x1
#define BIT1 0x2
#define BITS (BIT0 | BIT1)
flags = flags | BIT0;
```

- the `&` operator can be used to “mask off” one or more bits

```
test = flags & BITS;
```

- examples using 16-bit quantities

```
BIT0 = 0000000000000001
BIT1 = 0000000000000010
BITS = 0000000000000011
flags = 0100011100000001
flags | BITS = 0100011100000011
flags & BITS = 0000000000000001
```

## Shifting

---

- Shift operators: `<<` `>>`
  - $x \ll y$  shifts  $x$  **left**  $y$  bit positions
  - $x \gg y$  shifts  $x$  **right**  $y$  bit positions
- When shifting right:
  - if  $x$  is signed, shift may be **arithmetic** or **logical**
  - if  $x$  is unsigned, shift is **logical**
  - arithmetic shift fills with **sign bit**
  - logical shift fills with 0
- When shifting left, the vacated bits are always filled with 0
- Examples using 16-bit quantities

```
bits =      1100011100000001
bits << 2 = 0001110000000100
bits >> 2 = 1111000111000000 (arithmetic, with sign extension)
bits >> 2 = 0011000111000000 (logical)
```

## Assignment

---

- Assignment is an **operator**, not a statement

```
c = getchar();
if (c == EOF) ...
```

can be written as

```
if ((c = getchar()) == EOF) ...
```

- Watch out for “typos” like

```
if (c = EOF) ...
```

probably meant `==`; power tools can maim...

- “Augmented” assignment combines `+` `-` `*` `/` `%` `>>` `<<` `&` `^` `|` with `=`

```
i = i + 2           is the same as   i += 2
flags = flags | BIT0  flags |= BIT0;
e1 op= e2        is the same as   e1 = e1 op e2
                    except that e1 is evaluated once
```

- Watch out for precedence

```
x *= y + 1 means  x *= (y + 1)
                 not  (x *= y) + 1 (which is also legal)
```

## Conversions

---

- **Implicit** conversions occur in expressions and across assignments
- In expressions with mixed types, “Promote” to the “higher” type
 

```
int + float → float + float
short + long → long + long
```
- Watch out for sign extension! e.g. `char → int`

```
char c = '\377'; int i = c;
is i equal to 0377 or -1? when in doubt, mask: i = c&0377
```
- Assigning a “big” `int` to a “small” `int`, causes the extra bits to be **discarded**
- Assigning a `float` or `double` to an `int` **truncates**

```
int n = 2.5 assigns 2 to n
```
- **Explicit** conversions are specified with **casts**: *(type)expr*

```
sqrt((double)n)
(int)1.5
```
- study H&S, section 6.2 **carefully**

## Evaluation Order

---

- Except for `&&` and `||`, the evaluation order of expressions is **undefined**;
- Avoid expressions whose outcome might depend on evaluation order
 

```
x = f() + g();           use lint!
a[i] = i++;
f(++n, g(n));
```

Operators	Associativity
<code>() [] -&gt; .</code>	left to right
<code>! ~ ++ -- + - * &amp; (type) sizeof</code>	right to left
<code>* / %</code>	left to right
<code>+ -</code>	left to right
<code>&lt;&lt; &gt;&gt;</code>	left to right
<code>&lt; &lt;= &gt; &gt;=</code>	left to right
<code>== !=</code>	left to right
<code>&amp;</code>	left to right
<code>^</code>	left to right
<code> </code>	left to right
<code>&amp;&amp;</code>	left to right
<code>  </code>	left to right
<code>?:</code>	right to left
<code>= += -= /= %= &amp;= ^=  = &lt;&lt;= &gt;&gt;=</code>	right to left
<code>,</code>	left to right
