

# The Design of C

“C is quirky, flawed, and an enormous success. While accidents of history surely helped, it evidently satisfied a need for a system implementation language efficient enough to displace assembly language, yet sufficiently abstract and fluent to describe algorithms and interactions in a wide variety of environments.”

– Dennis Ritchie

# Goals of this Lecture

## Help you learn about:

- The decisions that were made by the designers\* of C
- **Why** they made those decisions  
... and thereby...
- The fundamentals of C

## Why?

- Learning the design rationale of the C language provides a richer understanding of C itself
- A power programmer knows both the programming language and its design rationale

\* Dennis Ritchie & members of standardization committees

# Goals of C

<b>Designers wanted C to:</b>	<b>But also:</b>
Support system programming	Support application programming
Be low-level	Be portable
Be easy for people to handle	Be easy for computers to handle

- Conflicting goals on multiple dimensions!
- Result: different design decisions than Java

# Operators

**Issue: What kinds of operators should C have?**

## Thought process

- Should handle typical operations
- Should handle bit-level programming ("bit twiddling")
- Should provide a mechanism for converting from one type to another

# Operators

## Decisions

- Provide typical arithmetic operators: `+` `-` `*` `/` `%`
- Provide typical relational operators: `==` `!=` `<` `<=` `>` `>=`
  - Each evaluates to 0  $\Rightarrow$  FALSE, 1  $\Rightarrow$  TRUE
- Provide typical logical operators: `!` `&&` `||`
  - Each interprets 0  $\Rightarrow$  FALSE, non-0  $\Rightarrow$  TRUE
  - Each evaluates to 0  $\Rightarrow$  FALSE, 1  $\Rightarrow$  TRUE
- Provide bitwise operators: `~` `&` `|` `^` `>>` `<<`
- Provide a cast operator: `(type)`

# Logical vs. Bitwise Ops

## Logical AND (&&) vs. bitwise AND (&)

- 2 (TRUE) && 1 (TRUE) => 1 (TRUE)

Decimal	Binary
2	00000000 00000000 00000000 00000010
&& 1	00000000 00000000 00000000 00000001
----	-----
1	00000000 00000000 00000000 00000001

- 2 (TRUE) & 1 (TRUE) => 0 (FALSE)

Decimal	Binary
2	00000000 00000000 00000000 00000010
& 1	00000000 00000000 00000000 00000001
----	-----
0	00000000 00000000 00000000 00000000

## Implication:

- Use **logical** AND to control flow of logic
- Use **bitwise** AND only when doing bit-level manipulation
- Same for OR and NOT

# Assignment Operator

## Issue: What about assignment?

### Thought process

- Must have a way to assign a value to a variable
- Many high-level languages provide an assignment **statement**
- Would be more expressive to define an assignment **operator**
  - Performs assignment, and then *evaluates to the assigned value*
  - Allows assignment to appear within larger expressions

### Decisions

- Provide assignment operator: =
- Define assignment operator so it changes the value of a variable, and also evaluates to that value

# Assignment Operator Examples

## Examples

```
i = 0;
/* Side effect: assign 0 to i.
   Evaluate to 0.

j = i = 0; /* Assignment op has R to L associativity */
/* Side effect: assign 0 to i.
   Evaluate to 0.
   Side effect: assign 0 to j.
   Evaluate to 0. */

while ((i = getchar()) != EOF) ...
/* Read a character.
   Side effect: assign that character to i.
   Evaluate to that character.
   Compare that character to EOF.
   Evaluate to 0 (FALSE) or 1 (TRUE). */
```

# Special-Purpose Assignment

## Issue: Should C provide tailored assignment operators?

### Thought process

- The construct `a = b + c` is flexible
- The construct `i = i + c` is somewhat common
- The construct `i = i + 1` is very common
- Special-purpose operators make code more expressive
  - Might reduce some errors
  - May complicate the language and compiler

### Decisions

- Introduce `+=` operator to do things like `i += c`
- Extend to `-=` `*=` `/=` `~=` `&=` `|=` `^=` `<<=` `>>=`
- Special-case increment and decrement: `i++` `i--`
- Provide both pre- and post-inc/dec: `x = ++i;` `y = i++;`

# iClicker Question

Q: What are `i` and `j` set to in the following code?

```
i = 5;  
j = i++;  
j += ++i;
```

- A. 5, 7
- B. 7, 5
- C. 7, 11
- D. 7, 12
- E. 7, 13

# sizeof Operator

## Issue: How to determine the sizes of data?

### Thought process

- The sizes of most primitive types are un- or under-specified
- Provide a way to find size of a given variable programmatically

### Decisions

- Provide a `sizeof` operator
  - Applied at compile-time
  - Operand can be a **data type**
  - Operand can be an **expression**,  
from which the compiler infers a data type

### Examples, on armlab using gcc217

- `sizeof(int)` evaluates to 4
- `sizeof(i)` – where `i` is a variable of type `int` – evaluates to 4

# iClicker Question

Q: What is the value of the following `sizeof` expression on the armlab machines?

```
int i = 1;
sizeof(i + 2L)
```

- A. 3
- B. 4
- C. 8
- D. 12
- E. error

# Other Operators

## Issue: What other operators should C have?

### Decisions

- Function call operator
  - Should mimic the familiar mathematical notation
  - `function(param1, param2, ...)`
- Conditional operator: `?:`
  - The only ternary operator: “inline if statement”
  - Example: `(i < j) ? i : j` evaluates to min of `i` and `j`
  - See King book for details
- Sequence operator (rarely used): `,`
  - See King book for details
- Pointer-related operators: `&` `*`
  - Described later in the course
- Structure-related operators: `.` `->`
  - Described later in the course

# Operators Summary: C vs. Java

## Java only

- `>>>` right shift with zero fill
- `new` create an object
- `instanceof` is left operand an object of class right operand?

## C only

- `->` structure member select
- `*` dereference
- `&` address of
- `,` sequence
- `sizeof` compile-time size of

# Control Statements: History

What the computer does  
“under the hood”:

```
/* add up numbers from 1 to  
   whatever is stored in R2 */  
1. R0 = 0  
2. R1 = 1  
3. compare R1, R2  
4. if greater goto 8  
5. R0 = R0 + R1  
6. R1 = R1 + 1  
7. goto 3  
8. /* answer in R0 */
```

Early programming  
languages (1950s)

```
/* add up numbers from 1 to n */  
  
sum = 0  
i = 1  
LOOP:  
if (i > n) goto DONE  
sum = sum + i  
i = i + 1  
goto LOOP  
DONE: /* answer in sum */
```

Some high-level conveniences (variable names, labels)  
but control flow based on **if** and **goto**

# Control Statements

## Algol-60 language (1960)

- BEGIN-END, IF-THEN-ELSE, WHILE-DO, FOR, (and also GOTO)

## Scientific background

- Boehm** and **Jacopini** proved (1966) that any algorithm *can* be expressed as the nesting of only 3 control structures:

Barry Boehm

### Sequence

### Selection

### Repetition

# Control Statements (cont.)

## Thought Process

- **Dijkstra** argued that any algorithm *should* be expressed using only those control structures (*GOTO Statement Considered Harmful*, 1968)

## C language design (1972)

- Basically follow ALGOL-60, but use { braces } instead of the more heavyweight BEGIN – END

Edsger Dijkstra

# Sequence Statement

**Compound statement, alias block**

```
{  
    statement1;  
    statement2;  
    ...  
}
```

# Selection Statements

**if** and **if...else** statements

```
if (expr)
    statement1;
```

```
if (expr)
    statement1;
else
    statement2;
```

# Selection Statements

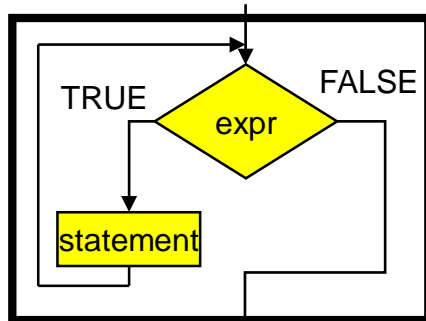

**switch** and **break** statements, for multi-path decisions on a single *integerExpr*

```
switch (integerExpr)
{  case integerLiteral1:
    ...
    break;
  case integerLiteral2:
    ...
    break;
  ...
  default:
    ...
}
```

What happens  
if you forget to  
**break**?

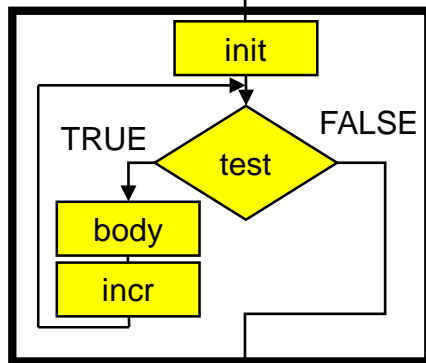

# Repetition Statements

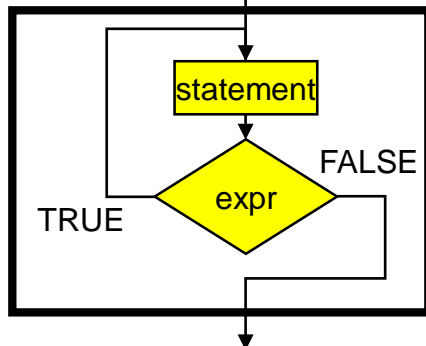

**while** statement: test at leading edge

```
while (expr)  
    statement;
```

**for** statement: test at leading edge,  
increment at trailing edge

```
for (initExpr; testExpr; incrExpr)  
    bodyStatement;
```

**do..while** statement: test at trailing edge

```
do  
    statement;  
while (expr);
```

# Other Control Statements

**Issue: What other control statements should C provide?**

## Decisions

- **break** statement
  - Breaks out of closest enclosing `switch` or repetition statement
- **continue** statement
  - Skips remainder of current loop iteration
  - Continues with next loop iteration
  - When used within `for`, still executes *incrementExpr*
- **goto** statement grudgingly provided
  - Jump to specified **label**

# Declaring Variables

**Issue: Should C require variable declarations?**

**Thought process:**

- Declaring variables allows compiler to check spelling
- Declaring variables allows compiler to allocate memory more efficiently
- Declaring variables produces fewer surprises about types of variables
- (But, requires more typing)

# Declaring Variables

## Decisions:

- Require variable declarations
- Provide **declaration statement**
- Programmer specifies type of variable (and other attributes too)

## Examples

- `int i;`
- `int i, j;`
- `int i = 5;`
- `const int i = 5; /* value of i cannot change */`
- `static int i; /* covered later in course */`
- `extern int i; /* covered later in course */`

# Declaring Variables

## Decisions (cont.):

- Unlike Java, declaration statements in C90 **must** appear before any other kind of statement in compound statement

```
{  
    int i;  
    /* Non-declaration  
       stmts that use i. */  
    ...  
    int j;  
    /* Non-declaration  
       stmts that use j. */  
    ...  
}
```

Illegal in C

```
{  
    int i;  
    int j;  
    /* Non-declaration  
       stmts that use i. */  
    ...  
    /* Non-declaration  
       stmts that use j. */  
    ...  
}
```

Legal in C

# Repetition Statements

## Decisions (cont.)

- Similarly, cannot declare loop control variable in `for` statement

```
{  
    ...  
    for (int i = 0; i < 10; i++)  
        /* Do something */  
    ...  
}
```

Illegal in C

```
{  
    int i;  
    ...  
    for (i = 0; i < 10; i++)  
        /* Do something */  
    ...  
}
```

Legal in C

# Statements Summary: C vs. Java

## Java only

- Declarations anywhere within block
- Declare immutable variables with **final**
- Conditionals of type **boolean**
- “Labeled” **break** and **continue**
- No **goto**

## C only

- Declarations only at beginning block
- Declare immutable variables with **const**
- Conditionals of any type (checked for zero / nonzero)
- No “labeled” **break** and **continue**
- **goto** provided (but using it in COS217 is a hanging offense)

# iClicker Question

Q: What does the following code print?

```
int i = 1;
switch (i++) {
    case 1: printf("%d", ++i);
    case 2: printf("%d", i++);
}
```

- A. 1
- B. 2
- C. 3
- D. 22
- E. 33

# I/O Facilities

## Issue: Should C provide I/O facilities?

### Thought process

- Unix provides the **file** abstraction
  - A file is a sequence of characters with an indication of the current position
- Unix provides 3 standard files
  - Standard input, standard output, standard error
- C should be able to use those files, and others
- I/O facilities are complex
- C should be small/simple

# I/O Facilities

## Decisions

- Do not provide I/O facilities in the **language**
- Instead provide I/O facilities in **standard library**
  - **Constant:** `EOF`
  - **Data type:** `FILE` (described later in course)
  - **Variables:** `stdin`, `stdout`, and `stderr`
  - **Functions:** ...

# Reading Characters

**Issue: What functions should C provide for reading characters from standard input?**

## Thought process

- Need function to read a single character from `stdin`
- Function must have a way to indicate failure, that is, to indicate that no characters remain

## Decisions

- Provide `getchar( )` function
- Make return type of `getchar( )` wider than `char`
  - Make it `int`; that's the natural word size
- Define `getchar( )` to return `EOF` (a special non-character `int`) to indicate failure

## Note

- There is no such thing as "the `EOF` character"

# Writing Characters

**Issue: What functions should C provide for writing a character to standard output?**

## Thought process

- Need function to write a single character to `stdout`

## Decisions

- Provide a `putchar ( )` function
- Define `putchar ( )` to accept one parameter
  - For symmetry with `getchar ( )`, parameter should be an `int`

# Reading Other Data Types

**Issue: What functions should C provide for reading data of other primitive types?**

## Thought process

- Must convert external form (sequence of character codes) to internal form
- Could provide `getshort()`, `getint()`, `getfloat()`, etc.
- Could provide one parameterized function to read any primitive type of data

## Decisions

- Provide `scanf()` function
- Can read any primitive type of data
- First parameter is a **format string** containing **conversion specifications**

See King book for details

# Writing Other Data Types

**Issue: What functions should C provide for writing data of other primitive types?**

## Thought process

- Must convert internal form to external form (sequence of character codes)
- Could provide `putshort()`, `putint()`, `putfloat()`, etc.
- Could provide one parameterized function to write any primitive type of data

## Decisions

- Provide `printf()` function
- Can write any primitive type of data
- First parameter is a **format string** containing **conversion specifications**

See King book for details

# Other I/O Facilities

## Issue: What other I/O functions should C provide?

### Decisions

- `fopen()`: Open a stream
- `fclose()`: Close a stream
- `fgetc()`: Read a character from specified stream
- `fputc()`: Write a character to specified stream
- `fgets()`: Read a line/string from specified stream
- `fputs()`: Write a line/string to specified stream
- `fscanf()`: Read data from specified stream
- `fprintf()`: Write data to specified stream

Described in King book, and later in the course after covering files, arrays, and strings

# Summary

## C design decisions and the goals that affected them

- Data types (last time)
- Operators
- Statements
- I/O facilities

Knowing the design goals and how they affected the design decisions can yield a rich understanding of C

# Appendix: The Cast Operator

Cast operator has multiple meanings:

(1) Cast between integer type and floating point type:

- Compiler generates code
- At run-time, code performs conversion

**f**    11000001110110110000000000000000    **-27.375**

**i = (int)f**

**i**    1111111111111111111111111111111100101    **-27**

# Appendix: The Cast Operator

## (2) Cast between floating point types of different sizes:

- Compiler generates code
- At run-time, code performs conversion

**f** `11000001110110110000000000000000` **-27.375**

**d = (double)f**

**d** `11000000001110110110000000000000  
00000000000000000000000000000000` **-27.375**

# Appendix: The Cast Operator

## (3) Cast between integer types of different sizes:

- Compiler generates code
- At run-time, code performs conversion

**i** 00000000000000000000000000000000000010 **2**

**c = (char) i**

**c** 00000010 **2**

# Appendix: The Cast Operator

## (4) Cast between integer types of same size:

- Compiler generates no code
- Compiler views given bit-pattern in a different way

`i`    `11111111111111111111111111111111111110`    **-2**

`u = (unsigned int)i`

`u`    `11111111111111111111111111111111111110`    **4294967294**
