Consensus: RAFT

COS 418: Distributed Systems
Lecture 14
Mike Freedman

RAFT slides based on those from Diego Ongaro and John Ousterhout.

RAFT Overview

1. Leader election
2. Normal operation (basic log replication)
3. Safety and consistency after leader changes
4. Neutralizing old leaders
5. Client interactions
6. Reconfiguration

Goal: Replicated Log

- Replicated log => replicated state machine
  - All servers execute same commands in same order
- Consensus module ensures proper log replication

Server States

- At any given time, each server is either:
  - Leader: handles all client interactions, log replication
  - Follower: completely passive
  - Candidate: used to elect a new leader
- Normal operation: 1 leader, N-1 followers
Liveness Validation

- Servers start as followers
- Leaders send heartbeats (empty AppendEntries RPCs) to maintain authority over followers
- If electionTimeout elapses with no RPCs (100-500ms), follower assumes leader has crashed and starts new election

Terms (aka epochs)

- Time divided into terms
  - Election (either failed or resulted in 1 leader)
  - Normal operation under a single leader
- Each server maintains current term value
- Key role of terms: identify obsolete information

Elections

- Start election:
  - Increment current term, change to candidate state, vote for self
- Send RequestVote to all other servers, retry until either:
  1. Receive votes from majority of servers:
     - Become leader
     - Send AppendEntries heartbeats to all other servers
  2. Receive RPC from valid leader:
     - Return to follower state
  3. No-one wins election (election timeout elapses):
     - Increment term, start new election

Elections

- Safety: allow at most one winner per term
  - Each server votes only once per term (persists on disk)
  - Two different candidates can't get majorities in same term
- Liveness: some candidate eventually wins
  - Each choose election timeouts randomly in \([T, 2T]\)
  - One usually initiates and wins election before others start
  - Works well if \(T >>\) network RTT
Log Structure

- Log entry = \( < \text{index}, \text{term}, \text{command} > \)
- Log stored on stable storage (disk); survives crashes
- Entry committed if known to be stored on majority of servers
  - Durable / stable, will eventually be executed by state machines

Normal operation

- Client sends command to leader
- Leader appends command to its log
- Leader sends AppendEntries RPCs to followers
- Once new entry committed:
  - Leader passes command to its state machine, sends result to client
  - Leader piggybacks commitment to followers in later AppendEntries
  - Followers pass committed commands to their state machines

Normal operation

- Crashed / slow followers?
  - Leader retries RPCs until they succeed

- Performance is “optimal” in common case:
  - One successful RPC to any majority of servers

Log Operation: Highly Coherent

- If log entries on different server have same index and term:
  - Store the same command
  - Logs are identical in all preceding entries

- If given entry is committed, all preceding also committed
Log Operation: Consistency Check

- AppendEntries has <index,term> of entry preceding new ones
- Follower must contain matching entry; otherwise it rejects
- Implements an induction step, ensures coherency

Leader Changes

- New leader's log is truth, no special steps, start normal operation
  - Will eventually make follower's logs identical to leader's
  - Old leader may have left entries partially replicated
- Multiple crashes can leave many extraneous log entries

Safety Requirement

- Raft safety property: If leader has decided log entry is committed, entry will be present in logs of all future leaders
- Why does this guarantee higher-level goal?
  1. Leaders never overwrite entries in their logs
  2. Only entries in leader's log can be committed
  3. Entries must be committed before applying to state machine

Picking the Best Leader

- Elect candidate most likely to contain all committed entries
  - In RequestVote, candidates incl. index + term of last log entry
  - Voter V denies vote if its log is "more complete":
    (newer term) or (entry in higher index of same term)
  - Leader will have "most complete" log among electing majority
**Committing Entry from Current Term**

- Case #1: Leader decides entry in current term is committed
  - **Safe:** leader for term 3 must contain entry 4

**Committing Entry from Earlier Term**

- Case #2: Leader trying to finish committing entry from earlier
  - Entry 3 not safely committed:
    - s₅ can be elected as leader for term 5 (how?)
    - If elected, it will overwrite entry 3 on s₁, s₂, and s₃

**New Commitment Rules**

- For leader to decide entry is committed:
  1. Entry stored on a majority
  2. ≥ 1 new entry from leader's term also on majority
- Example: Once e₄ committed, s₅ cannot be elected leader for term 5, and e₃ and e₄ both safe

**Challenge: Log Inconsistencies**

- Leader changes can result in log inconsistencies
Neutralizing Old Leaders

- Leader temporarily disconnected
  - Other servers elect new leader
  - Old leader reconnected
  - Old leader attempts to commit log entries

- Terms used to detect stale leaders (and candidates)
  - Every RPC contains term of sender
  - Sender's term < receiver:
    - Receiver: Rejects RPC (via ACK which sender processes...)
    - Receiver's term < sender:
      - Receiver reverts to follower, updates term, processes RPC

- Election updates terms of majority of servers
  - Deposited server cannot commit new log entries

Client Protocol

- Send commands to leader
  - If leader unknown, contact any server, which redirects client to leader

- Leader only responds after command logged, committed, and executed by leader

- If request times out (e.g., leader crashes):
  - Client reissues command to new leader (after possible redirect)

- Ensure exactly-once semantics even with leader failures
  - E.g., Leader can execute command then crash before responding
    - Client should embed unique request ID in each command
    - This unique request ID included in log entry
    - Before accepting request, leader checks log for entry with same ID
RECONFIGURATION

Configuration Changes

- View configuration: \{ leader, \{ members \}, settings \}
- Consensus must support changes to configuration:
  e.g., replace failed machine, change degree of replication
- Cannot switch directly from one config to another: conflicting majorities could arise

- Joint consensus in intermediate phase: need majority of both old and new configurations for elections, commitment
- Configuration change just a log entry; applied immediately on receipt (committed or not)
- Once joint consensus is committed, begin replicating log entry for final config

2-Phase Approach via Joint Consensus
- Any server from either configuration can serve as leader
- If leader not in \( C_{new} \), must step down once \( C_{new} \) committed
