## 4.3 DATA STRUCTURES

---

- ▶ *collections*
- ▶ *stacks and queues*
- ▶ *linked lists*
- ▶ *symbol tables*
- ▶ *Java collections framework*

# Data structures

---

**Data structure.** Method for organizing data in a computer so that it can be accessed efficiently.

category	data structures
<i>array</i>	1D array, resizing array, binary heap, Bloom filter, <b>ring buffer</b> , ...
<i>linked list</i>	singly linked list, doubly linked list, blockchain, ...
<i>tree</i>	binary search tree, k-d tree, Merkle tree, B-tree, decision tree, ...
<i>composite</i>	2D array, hash table, tensor, sparse matrix, graph, ...

The image contains three diagrams. On the left is a horizontal array of four blue boxes labeled 0, 1, 2, and 3 above them. In the center is a horizontal linked list of four blue circles connected by arrows pointing to the right. On the right is a binary tree with a root node connected to two children, which are further connected to four leaf nodes.

*Guitar Hero*

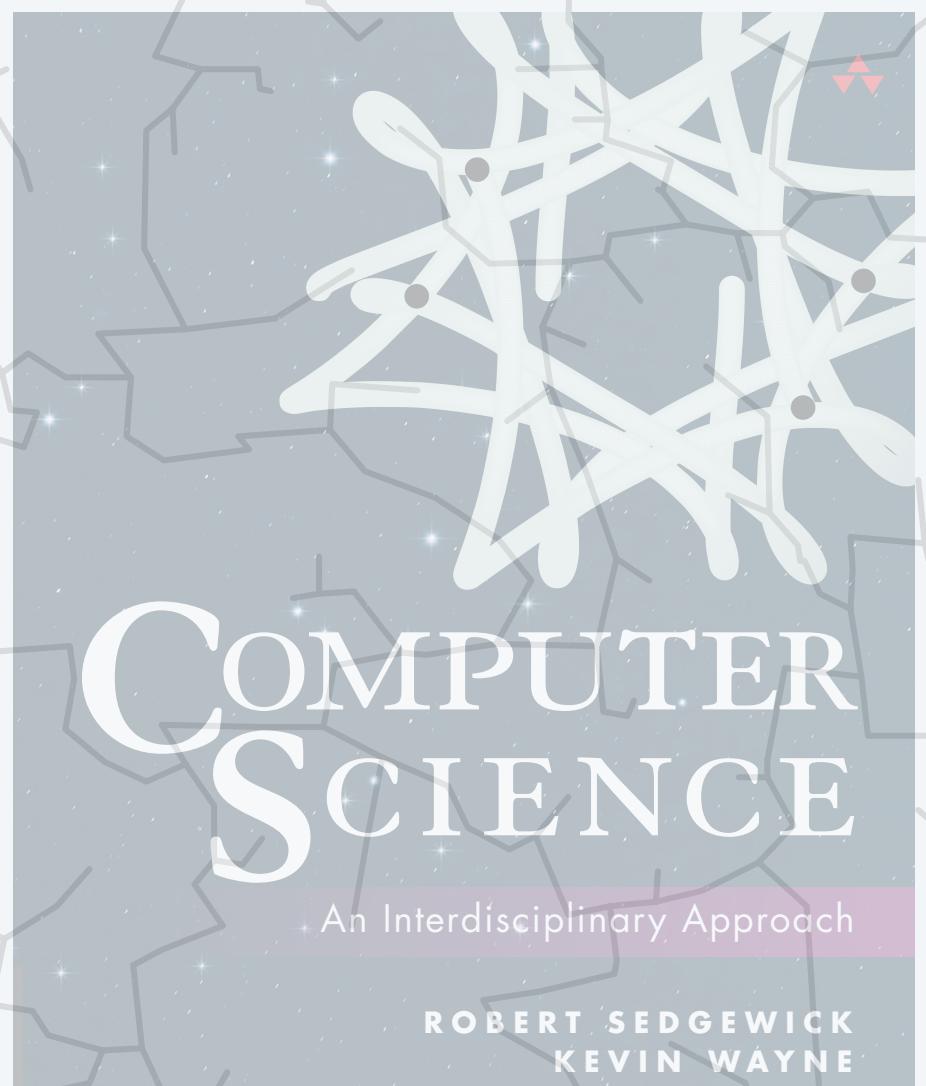

# Collections

---

A **collection** is a data type that stores a group of related items.

collection	core operations	data structure
<i>stack</i>	PUSH, POP	singly linked list resizing array
<i>queue</i>	ENQUEUE, DEQUEUE	
<i>symbol table</i>	PUT, GET, DELETE	binary search tree hash table
<i>set</i>	ADD, CONTAINS, DELETE	
:	:	:

## 4.3 DATA STRUCTURES

---

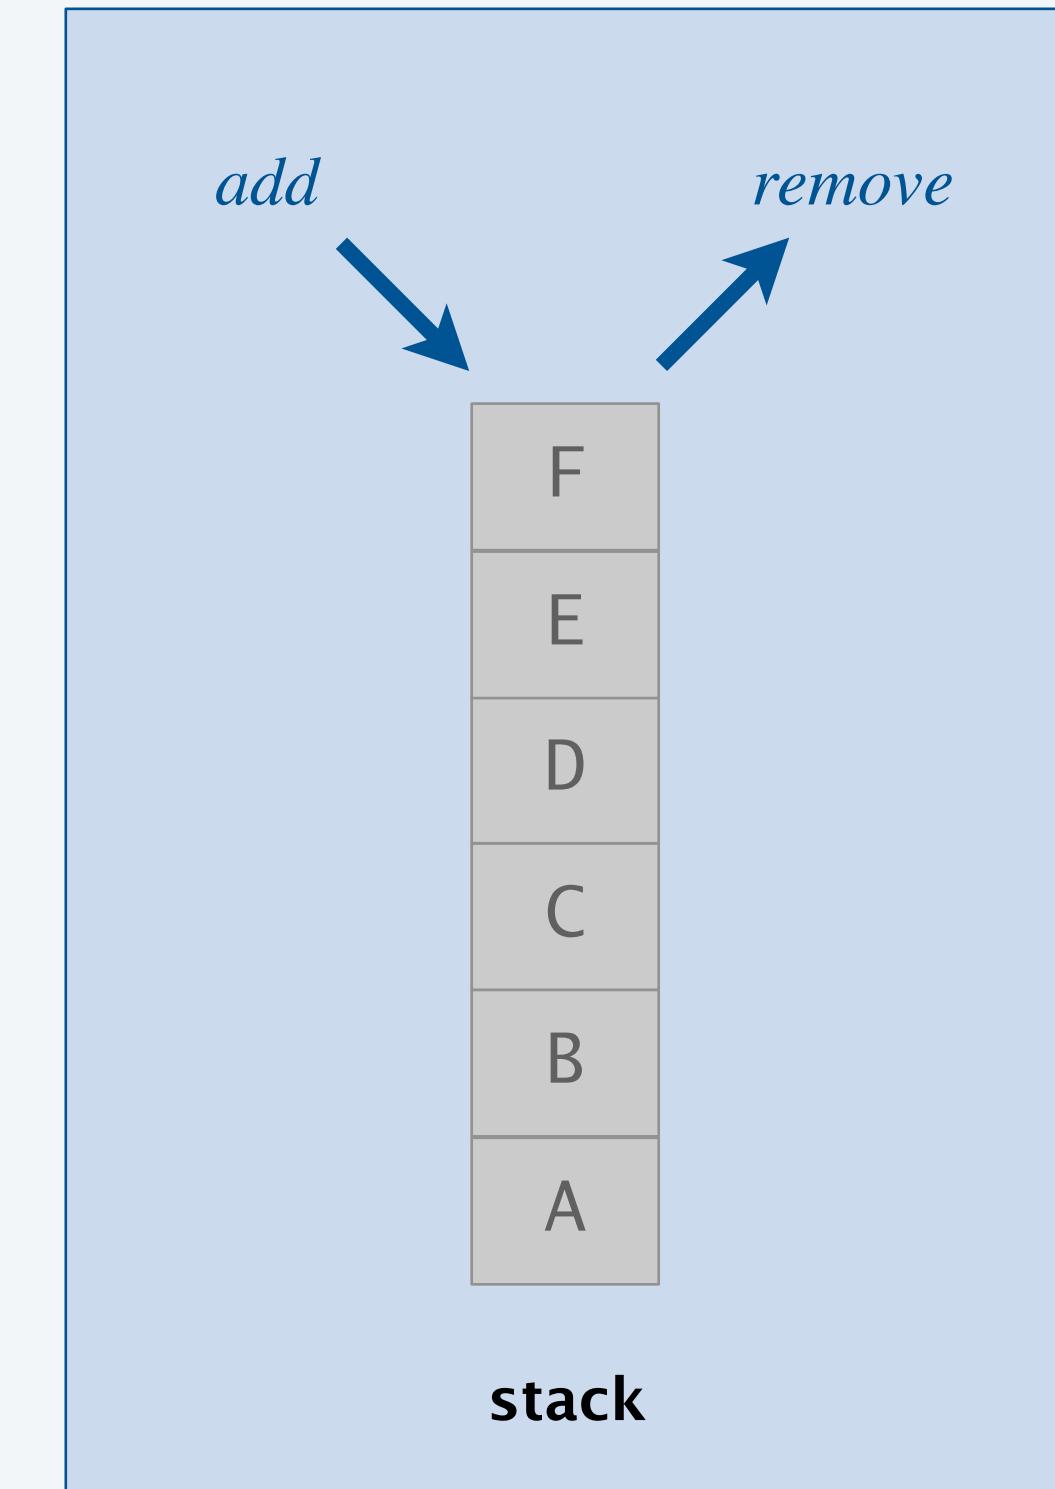

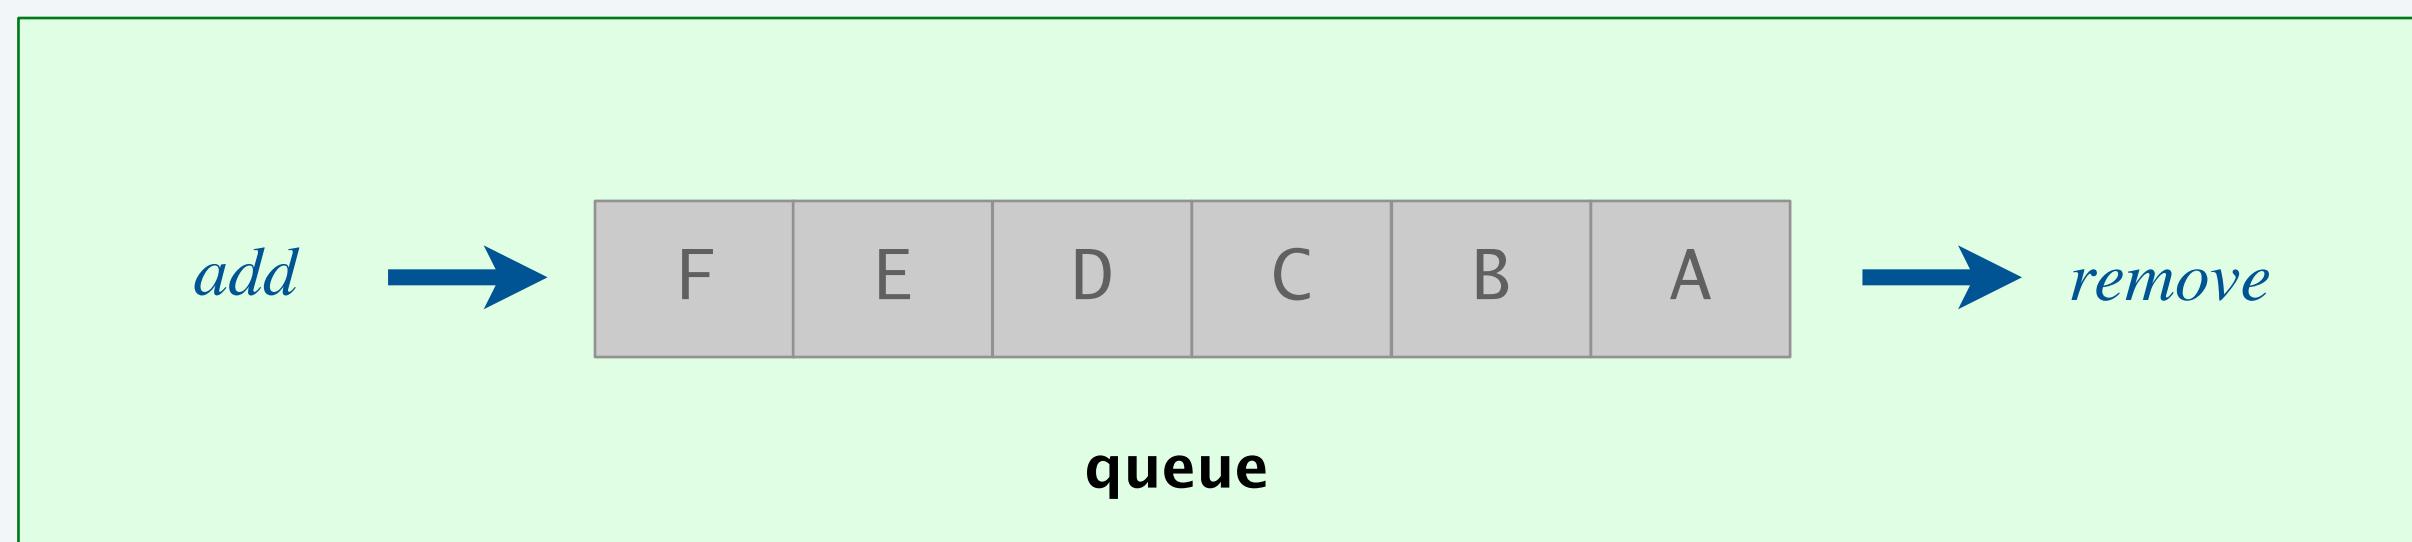

- ▶ *collections*
- ▶ *stacks and queues*
- ▶ *linked lists*
- ▶ *symbol tables*
- ▶ *Java collections framework*

# Stacks and queues

## Fundamental data types.

- Value: **collection** of objects.
- Operations: **add**, **remove**, iterate, size, test if empty.
- Intent is clear when we add.
- Which item do we remove?

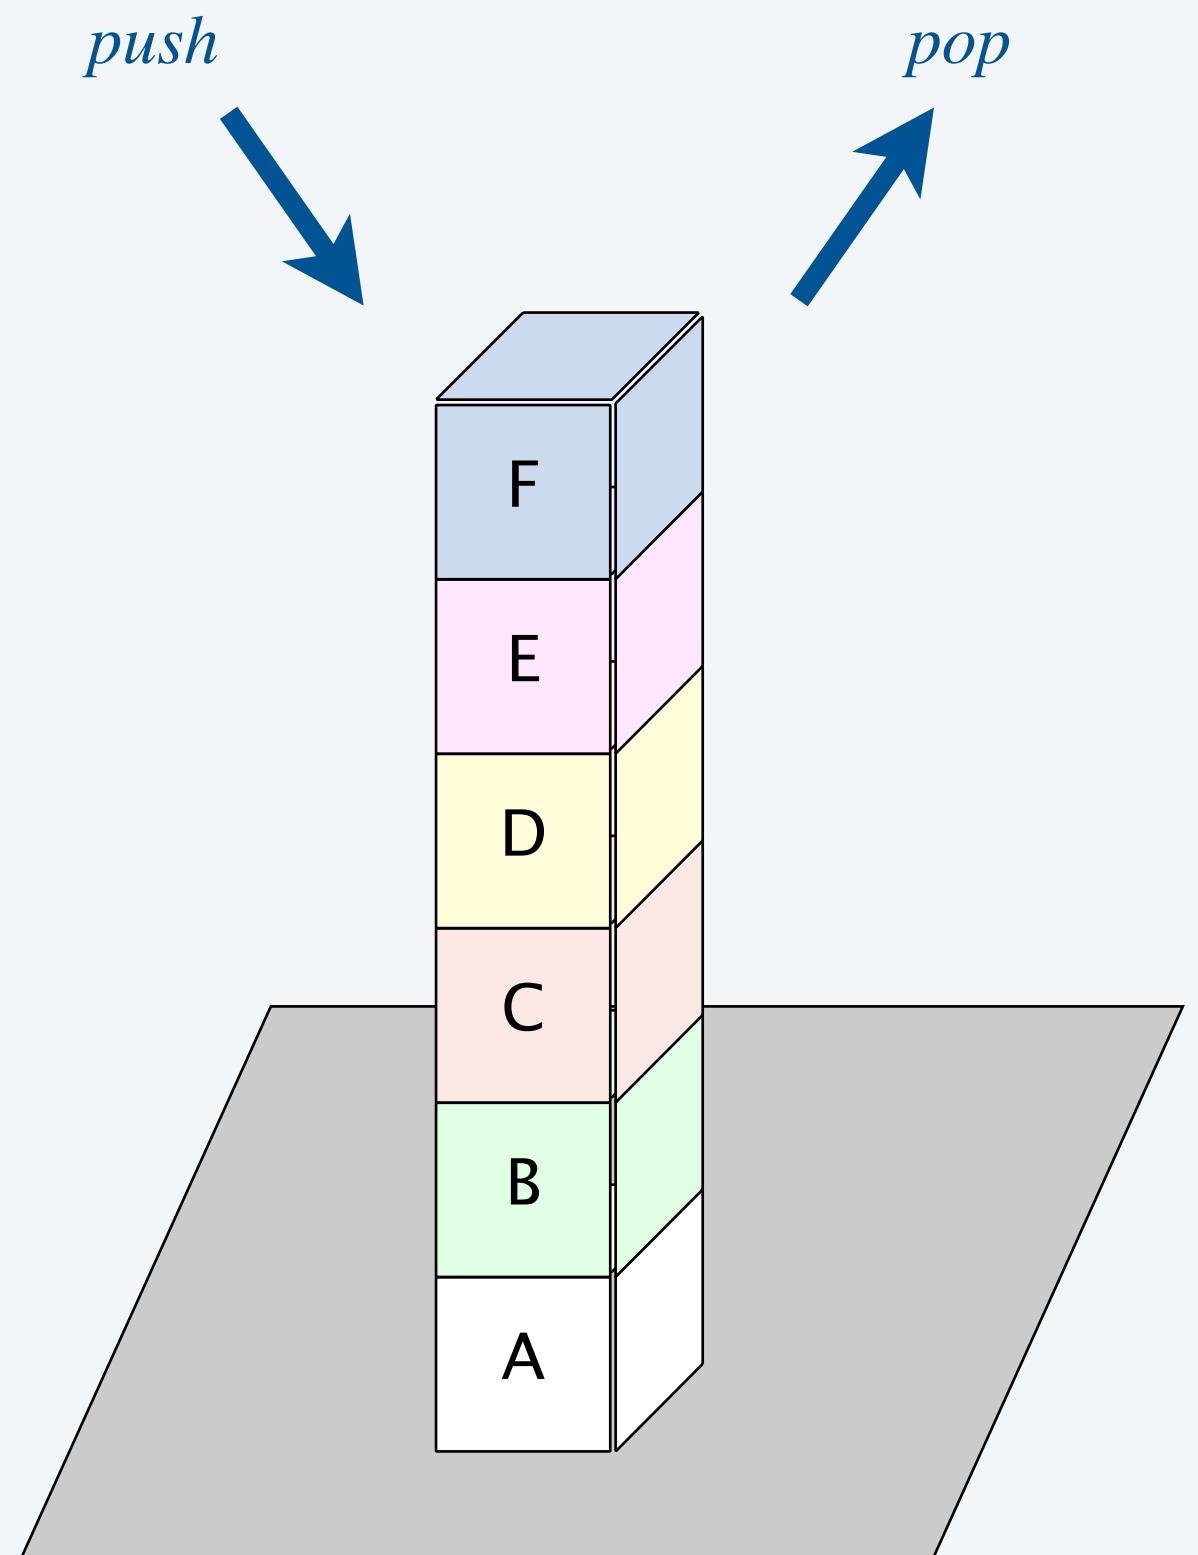

**Stack.** Remove the item **most** recently added.  $\leftarrow$  *LIFO = “last in first out”*

**Queue.** Remove the item **least** recently added.  $\leftarrow$  *FIFO = “first in first out”*

Stack data type. Our textbook data type for stacks. ←

*available with javac-introcs  
and java-introcs commands*

		description
<code>public class Stack&lt;Item&gt;</code>		<i>“generic type parameter”</i>
	<code>Stack()</code>	<i>create an empty stack</i>
<code>void</code>	<code>push(Item item)</code>	<i>add a new item to the stack</i>
<code>Item</code>	<code>pop()</code>	<i>remove and return the item most recently added</i>
<code>boolean</code>	<code>isEmpty()</code>	<i>is the stack empty?</i>
<code>int</code>	<code>size()</code>	<i>number of items on the stack</i>

Performance requirements. Every operation takes constant time.

# Stack warmup client

**Goal.** Read strings from standard input and print in **reverse order**.

- Read strings from standard input and push onto stack.
- Pop all strings from stack and print.

```
public class Reverse {  
    public static void main(String[] args) {  
        Stack<String> stack = new Stack<String>(); ← create stack  
        while (!StdIn.isEmpty()) {  
            String s = StdIn.readString();  
            stack.push(s); ← push strings onto stack  
        }  
  
        while (!stack.isEmpty()) {  
            String s = stack.pop();  
            StdOut.print(s + " "); ← pop strings from stack and print  
        }  
        StdOut.println();  
    }  
}
```

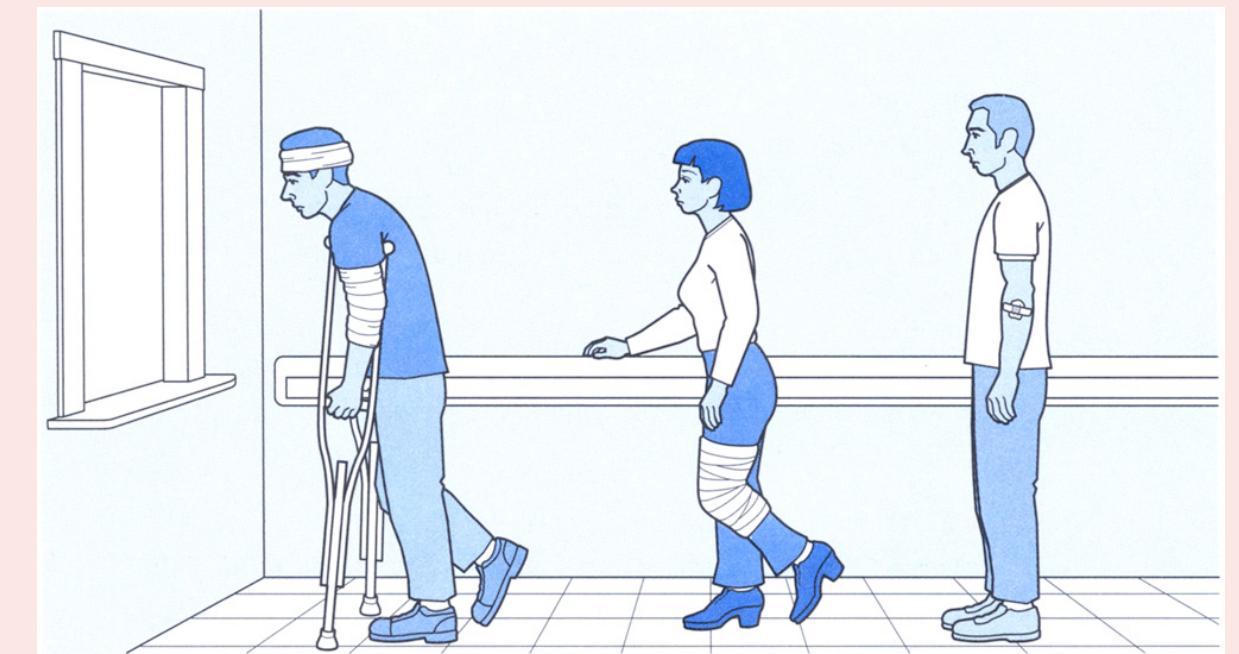

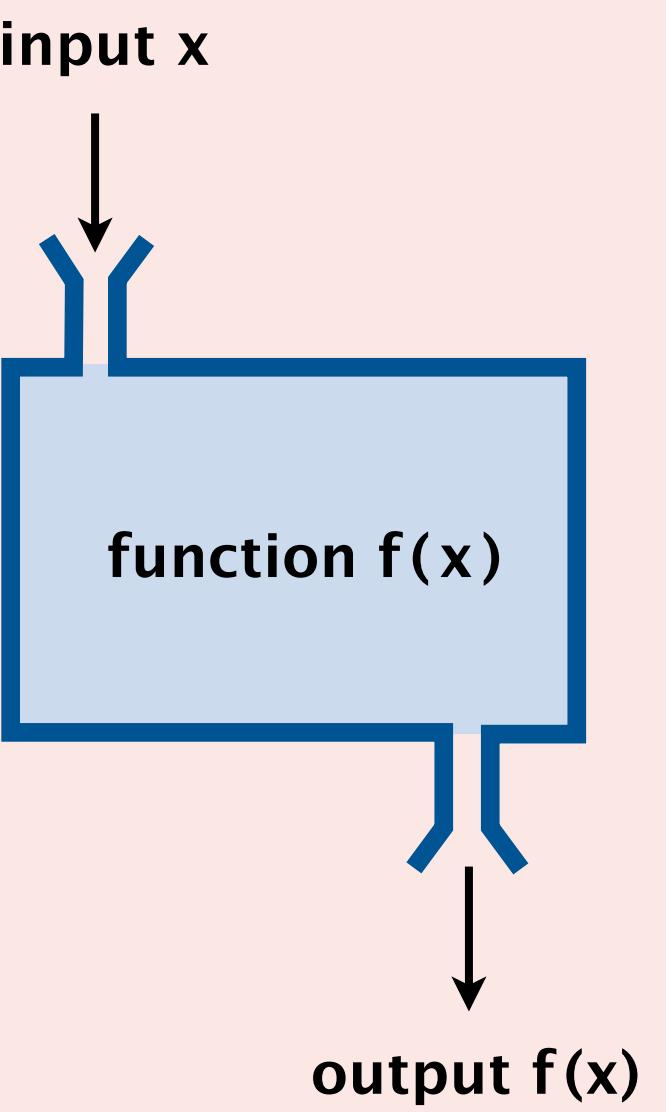

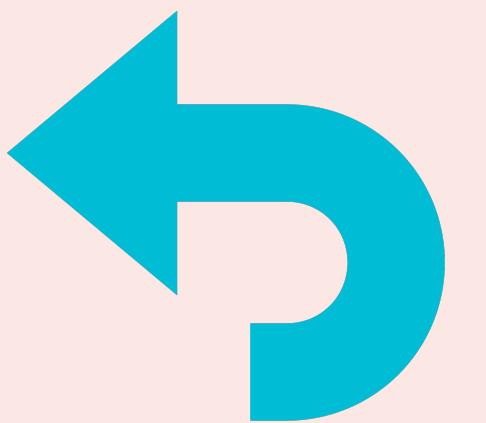

*“type argument”*  
(can be any reference type)

```
~/cos126/ds> java-introcs Reverse  
I have a dream today  
<Ctrl-D>  
today dream a have I
```

Which would **not** be implemented with a stack?

- A. Back button in a browser.
- B. Undo in a word processor.
- C. Function-call stack.
- D. Triage in a hospital.

# Function-call stack demo

```
public static double square(double a) {  
    return a*a;  
}
```

variable	a
value	3.0

square(3.0)

hypotenuse(3.0, 4.0)

main()

function-call stack

# Arithmetic expression evaluation

---

**Goal.** Write a program to evaluate **infix expressions**.

$( 1 + ( ( 2 + 3 ) * ( 4 * 5 ) ) )$  ← *for simplicity, fully parenthesized and tokens separated by whitespace*

↑      ↑  
*operand    operator*  
*(value)*

**Solution.** Dijkstra's two-stack algorithm. [see demo]

**Context.** An interpreter!

↑  
*a program that executes  
instructions (e.g., infix expressions)  
without compiling to machine language*

# Dijkstra's two-stack algorithm demo

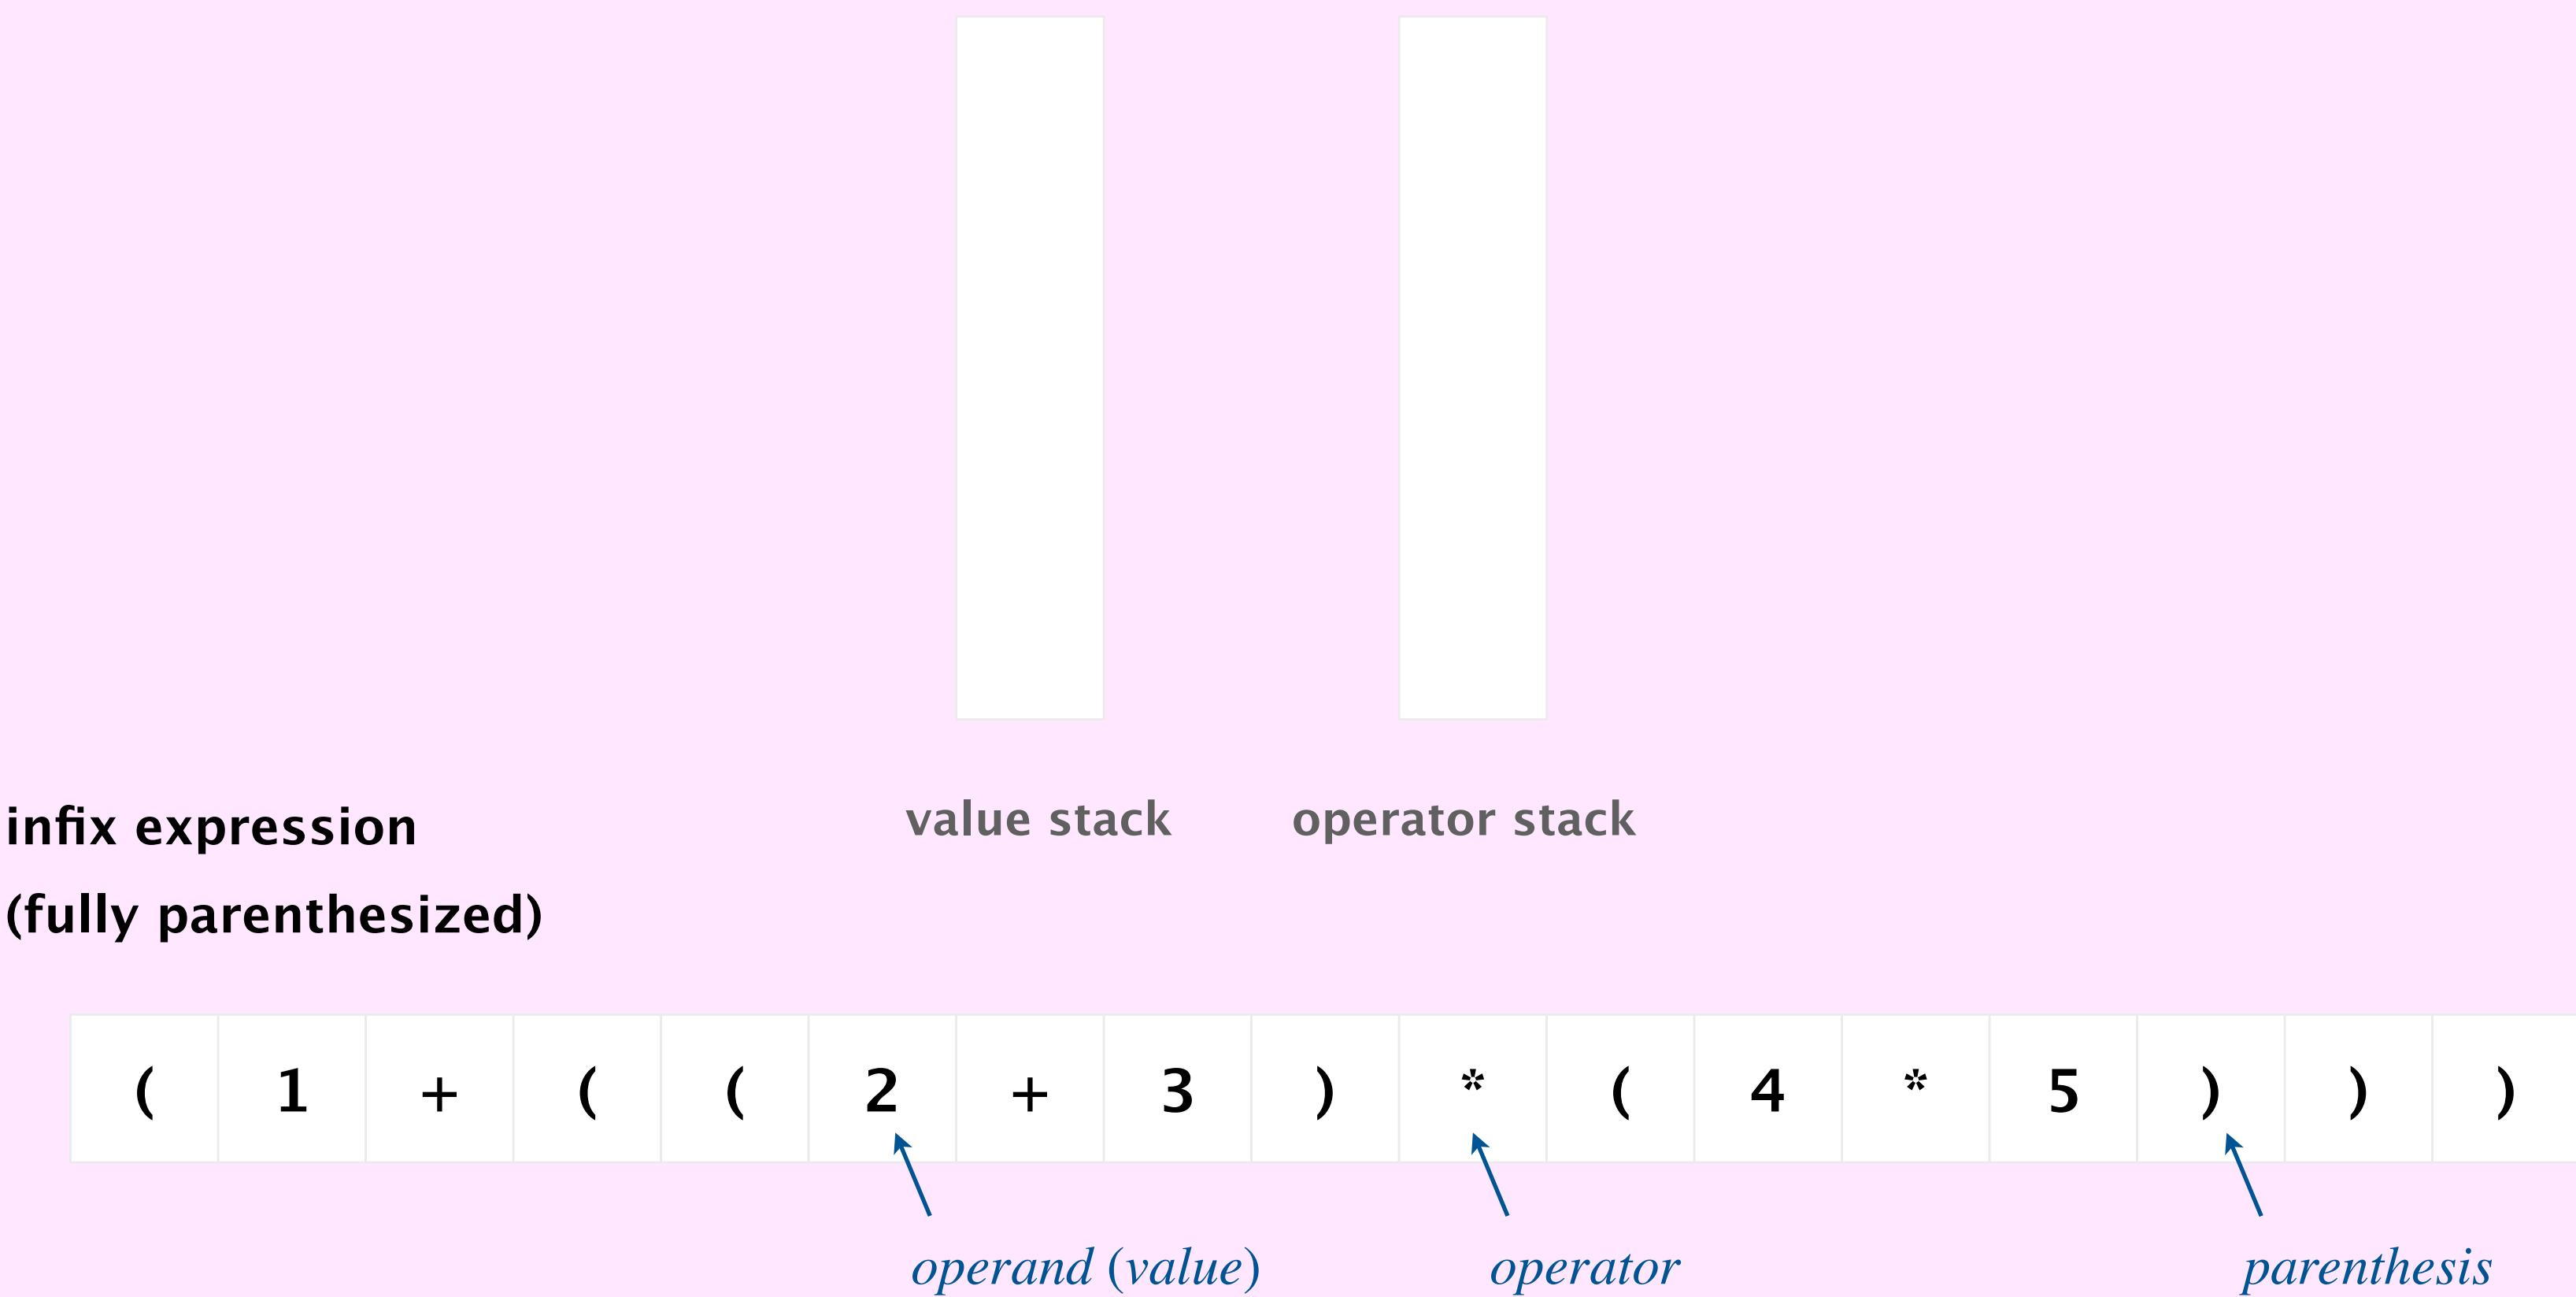

Value: push onto the value stack.

Operator: push onto the operator stack.

Left parenthesis: ignore.

Right parenthesis: pop operator and two values; push the result onto the value stack.

*of applying that operator  
to those two values*

## How to declare and initialize a stack of doubles in Java?

- A. `Stack<double> stack = new Stack();`
- B. `Stack<double> stack = new Stack<double>();`
- C. `Stack stack = new Stack();`
- D. None of the above.

# Arithmetic expression evaluation: Java implementation

```
public class Evaluate {  
    public static void main(String[] args) {  
        Stack<String> ops = new Stack<String>();  
        Stack<Double> vals = new Stack<Double>(); ← for stack of primitive type,  
                                                need to use “wrapper” type  
  
        while (!StdIn.isEmpty()) {  
            String s = StdIn.readString();  
            if (s.equals("(")) /* no-op */ ;  
            else if (s.equals("+")) ops.push(s);  
            else if (s.equals("*")) ops.push(s);  
            else if (s.equals(")")) {  
                String op = ops.pop();  
                if (op.equals("+")) vals.push(vals.pop() + vals.pop());  
                else if (op.equals("*")) vals.push(vals.pop() * vals.pop()); ← careful with non-commutative  
                                                operators such as - and /  
                                                (Java evaluates functions left-to-right)  
            }  
            else vals.push(Double.parseDouble(s)); ← token is a number  
        }  
  
        StdOut.println(vals.pop()); ← result is last element of stack  
    }  
}
```

```
~/cos126/ds> java-introcs Evaluate  
( 1 + 2 ) ← fully parenthesized and  
3.0 tokens separated by whitespace  
~/cos126/ds> java-introcs Evaluate  
( 1 + ( ( 2 + 3 ) * ( 4 * 5 ) ) )  
101.0
```

## Arithmetic expression evaluation: correctness

---

Q. Why correct?

A. When algorithm encounters an operator surrounded by two values within parentheses, it leaves the result on the value stack.

$$(1 + (\underline{(2 + 3)} * (4 * 5)))$$

as if the original input were:

$$(1 + (\underline{5} * (4 * 5)))$$

Repeating the argument:

$$(1 + (5 * 20))$$
$$(1 + 100)$$

101

Extensions. More operators, precedence order, associativity, ...

# Stack-based programming languages

---

**Observation 1.** Dijkstra's two-stack algorithm computes the same value if each operator occurs **after** the two corresponding operands.

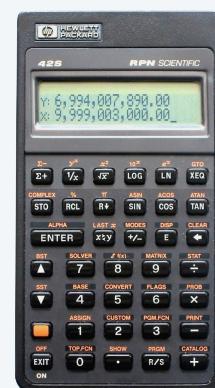

$$\begin{aligned} & (1 + ((2 + 3) * (4 * 5))) \\ & (1 ( (2 3 + ) (4 5 * ) * ) + ) \quad \text{← } \textit{operator after operands} \end{aligned}$$

**Observation 2.** All of the parentheses are redundant!  $\leftarrow$  *every right parenthesis is now preceded by an operator*

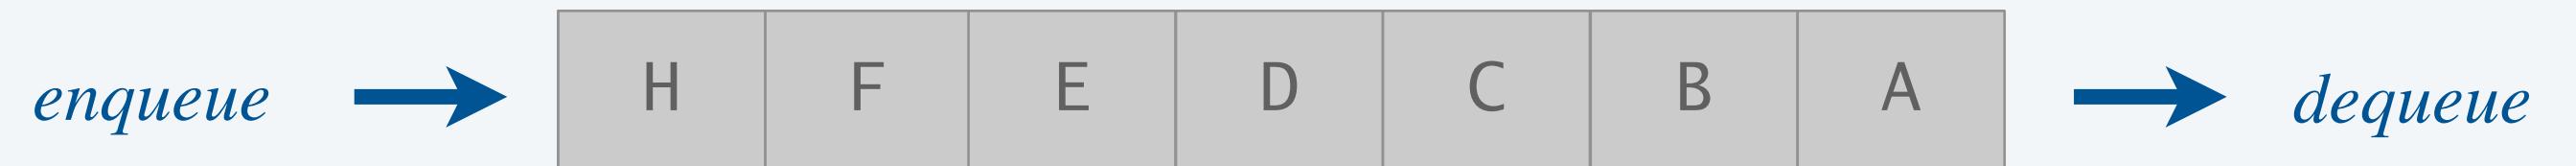

1 2 3 + 4 5 \* \* +

**Bottom line.** Postfix or “reverse Polish” notation (RPN).

**Applications.** PostScript, PDF, Java virtual machine, RPL, ...

Queue data type. Our textbook data type for queues.

public class Queue<Item>

**description**

Queue()

*create an empty queue*

void enqueue(Item item)

*add a new item to the queue*

Item dequeue()

*remove and return the item least recently added*

boolean isEmpty()

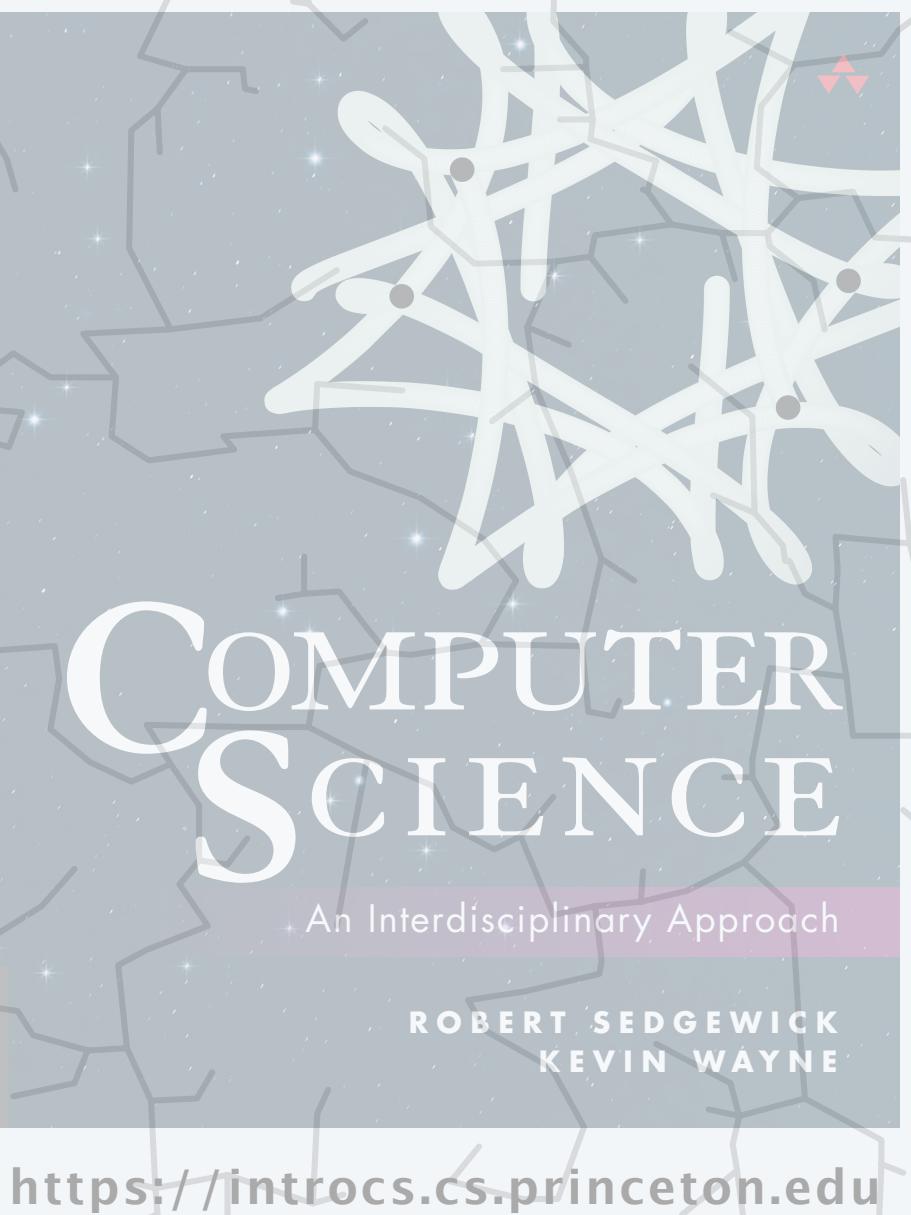

*is the queue empty?*

int size()

*number of items on the queue*

Performance requirements. Every operation takes constant time.

## 4.3 DATA STRUCTURES

---

- ▶ *collections*
- ▶ *stacks and queues*
- ▶ ***linked lists***
- ▶ *symbol tables*
- ▶ *Java collections framework*

# Stack implementation with a linked list

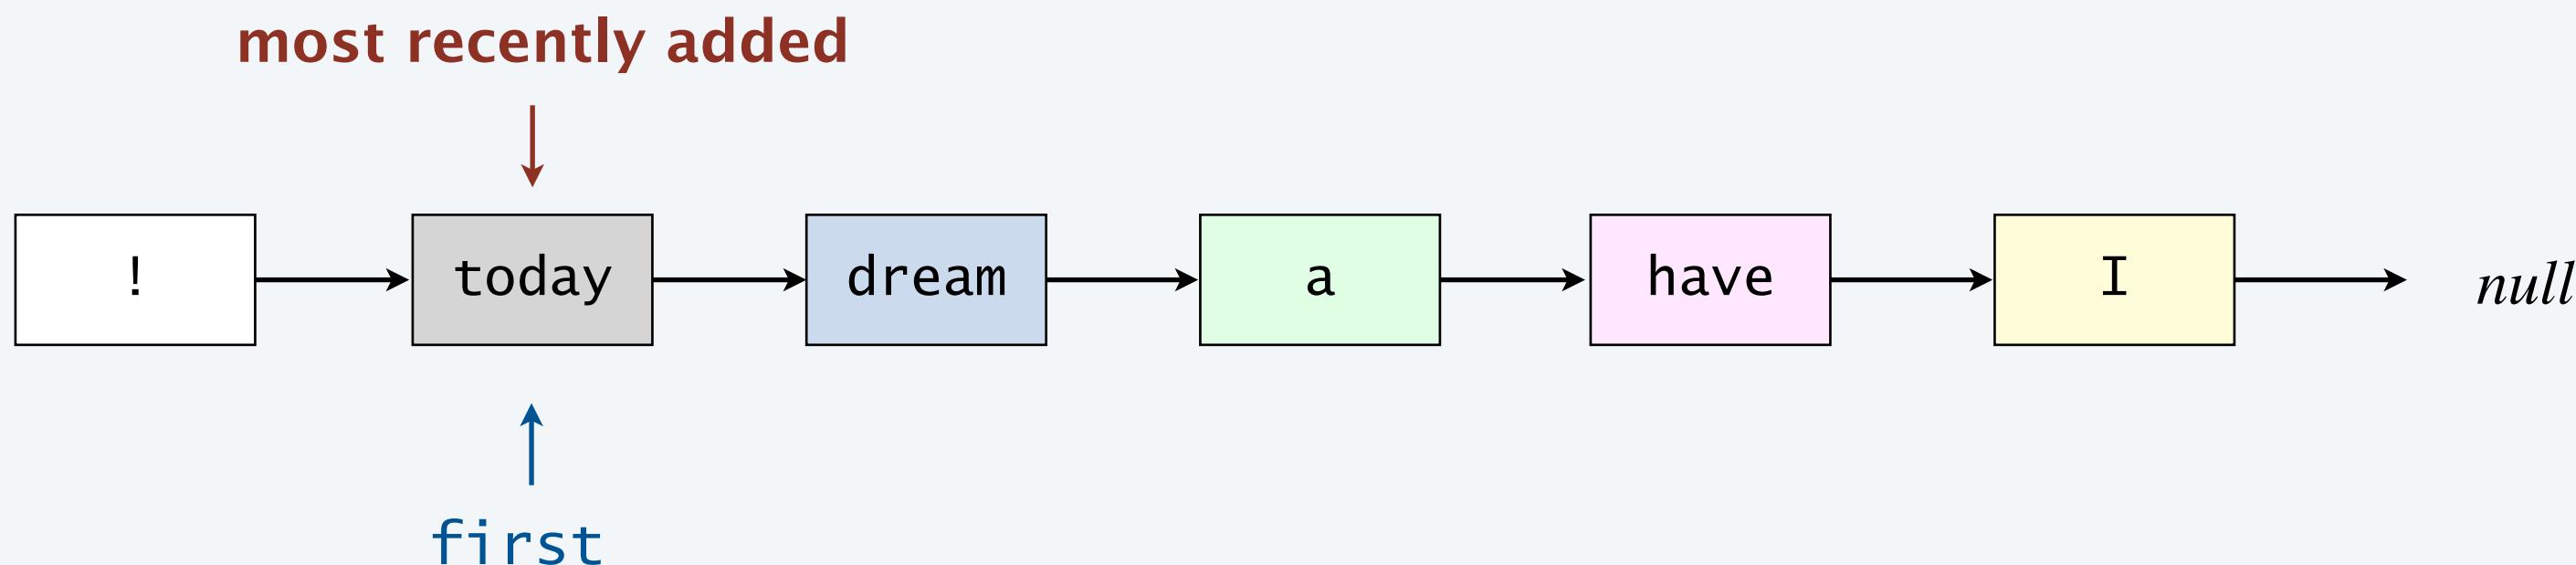

---

Q. How to implement a stack (or queue)?

Main challenge. Don't know how many items will be on the stack. ← *otherwise, could use an array*

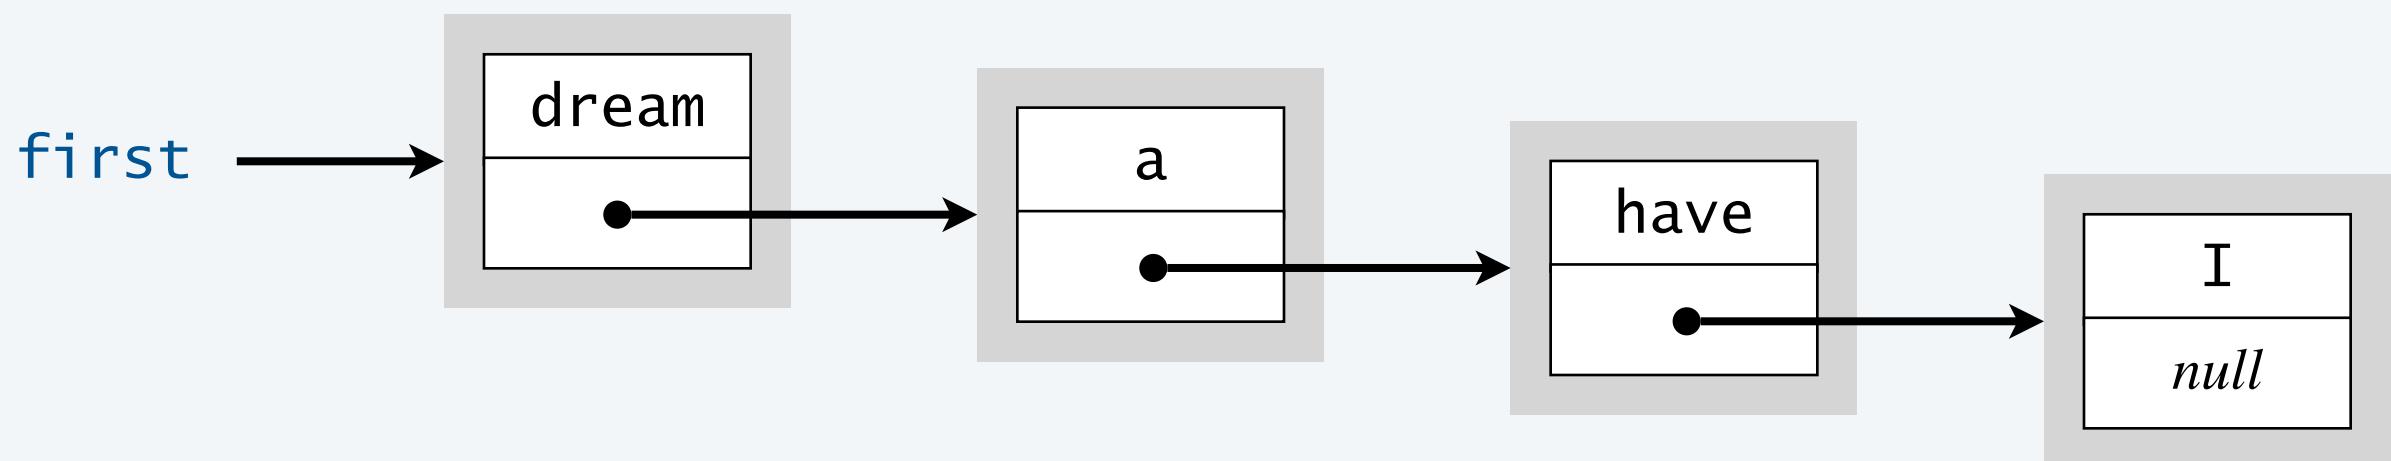

An elegant solution. Use a **singly linked list**.

- A **node** contains an item and a reference to the next node in the sequence.
- Maintain reference **first** to first node.
- Push new item before **first**.
- Pop item from **first**.

# Stack implementation with a linked list: pop

singly linked list

save item to return

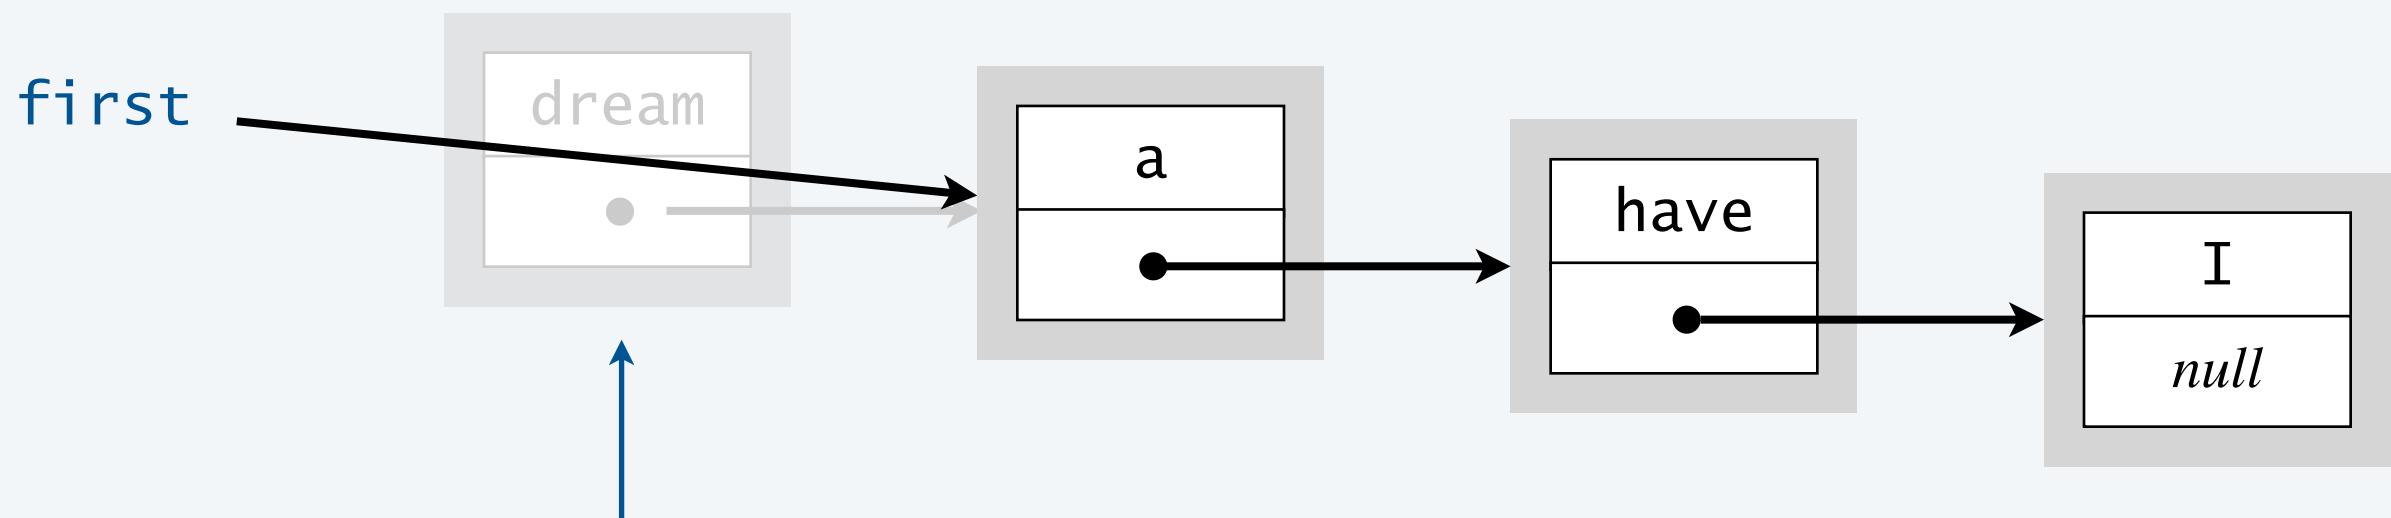

```
String item = first.item;
```

delete first node

```
first = first.next;
```

return saved item

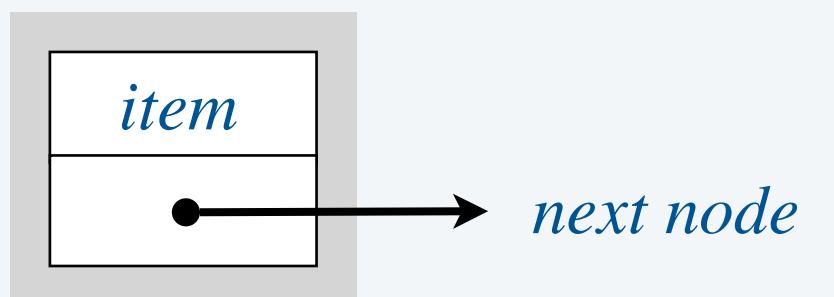

```
return item;
```

*garbage collector reclaims memory  
when no remaining references*

nested class

```
private class Node {  
    private String item;  
    private Node next;  
}
```

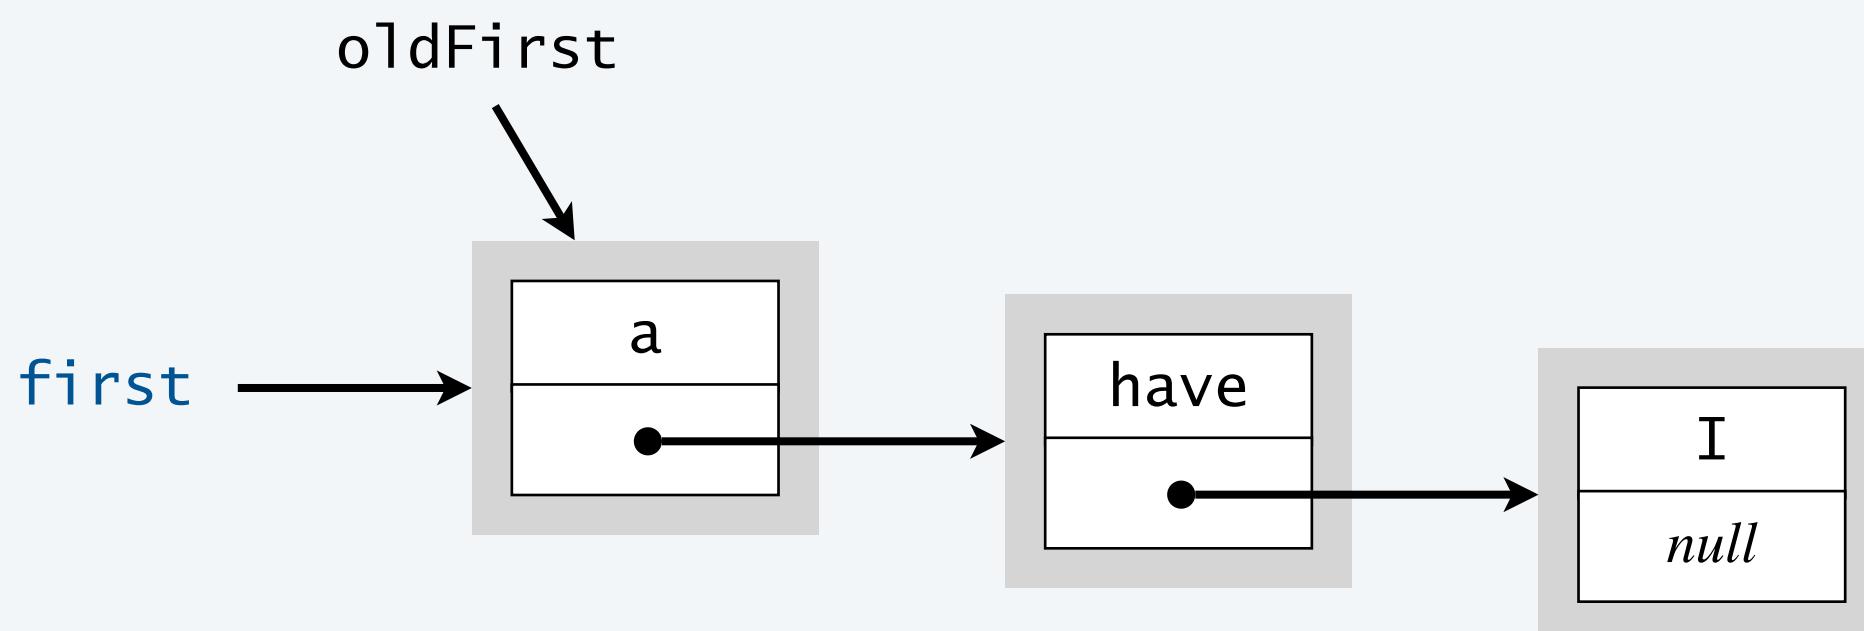

Node

# Stack implementation with a linked list: push

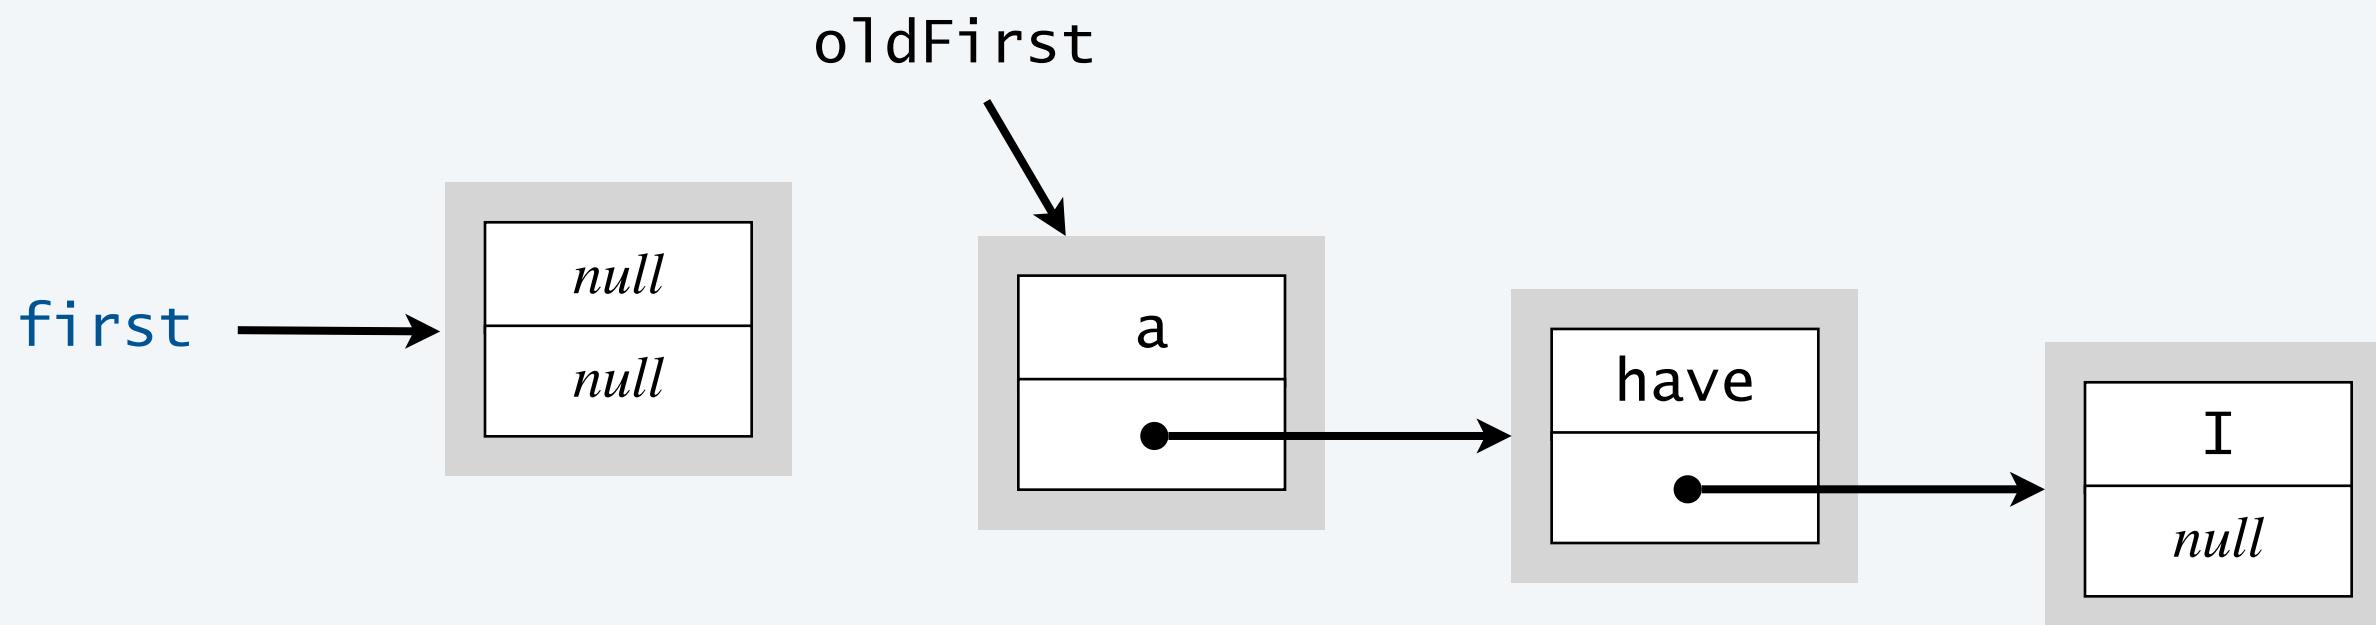

save a link to the list

```
Node oldFirst = first;
```

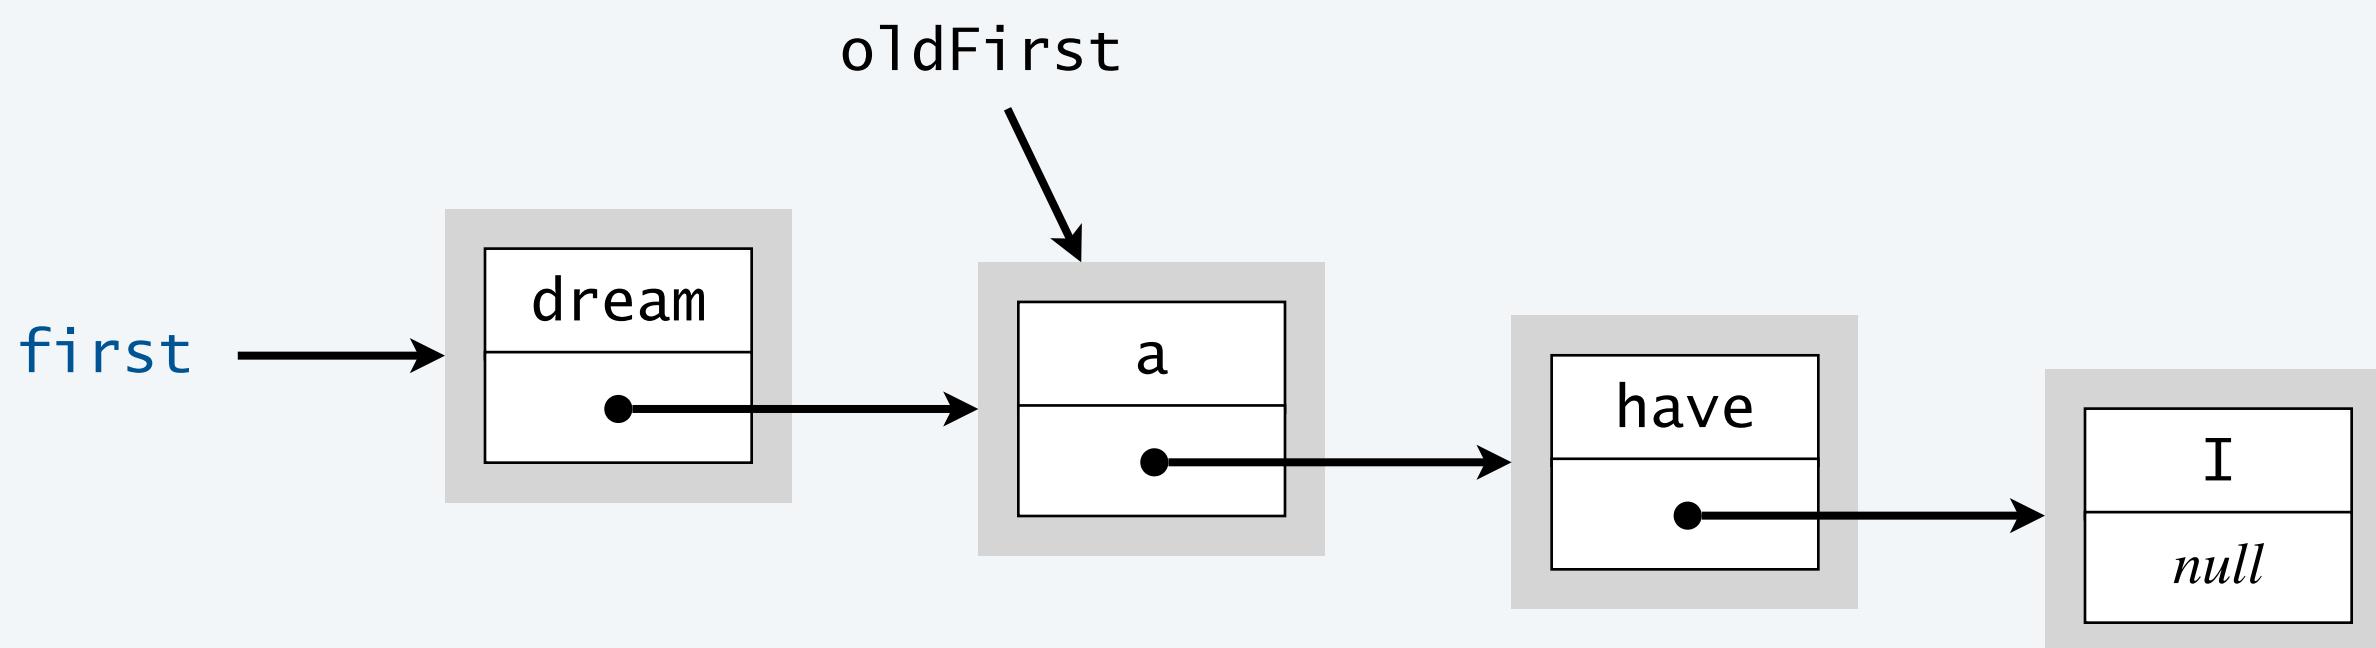

create a new node at the front

```
first = new Node();
```

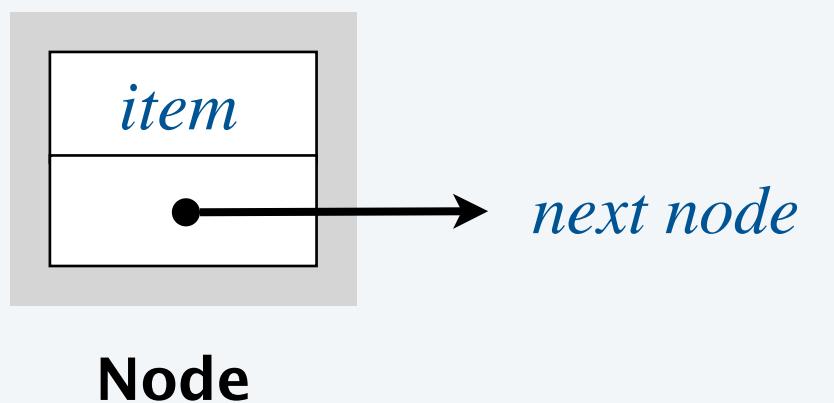

initialize the instance variables in the new Node

```
first.item = "dream";  
first.next = oldFirst;
```

nested class

```
private class Node {  
    private String item;  
    private Node next;  
}
```

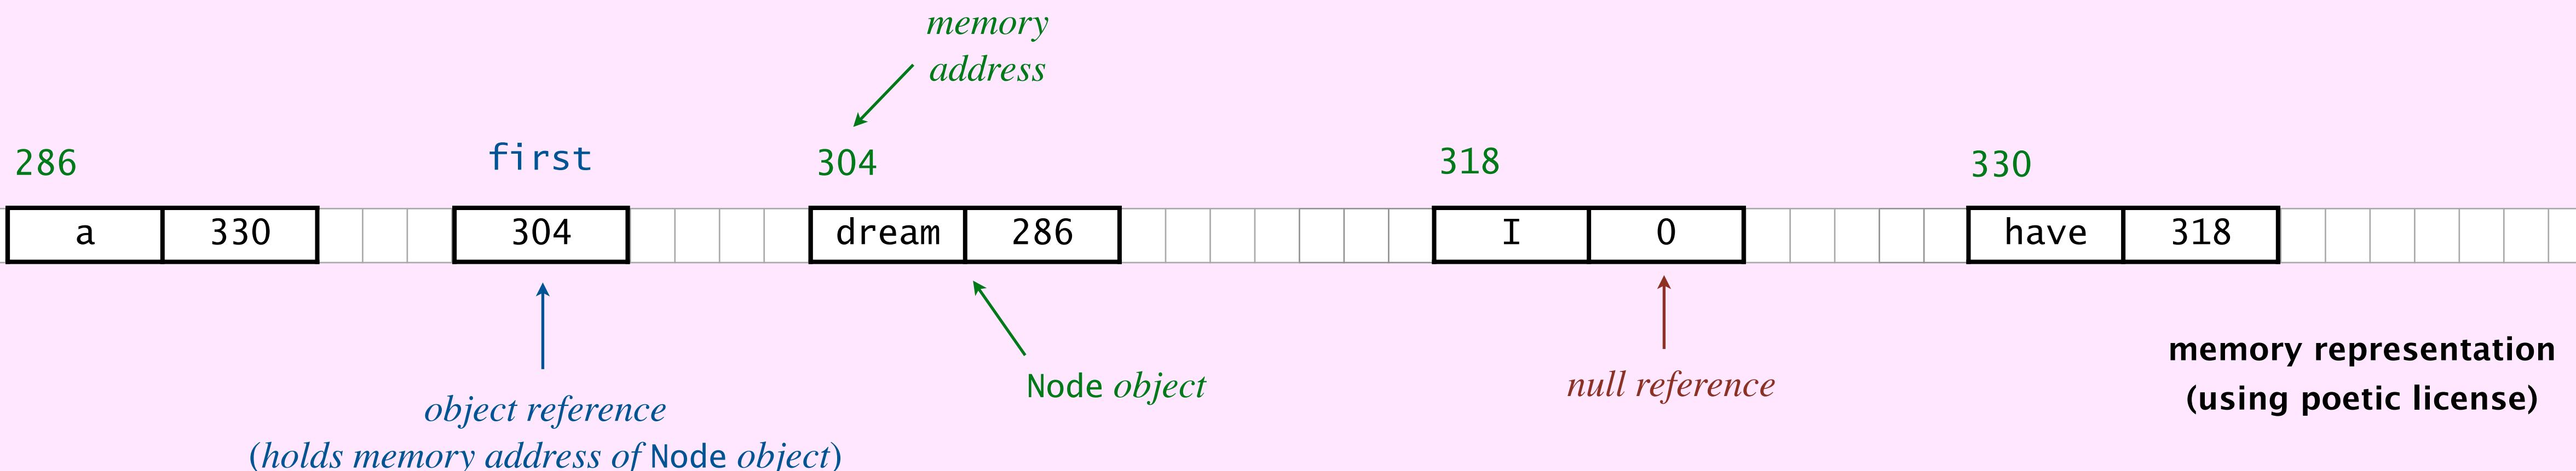

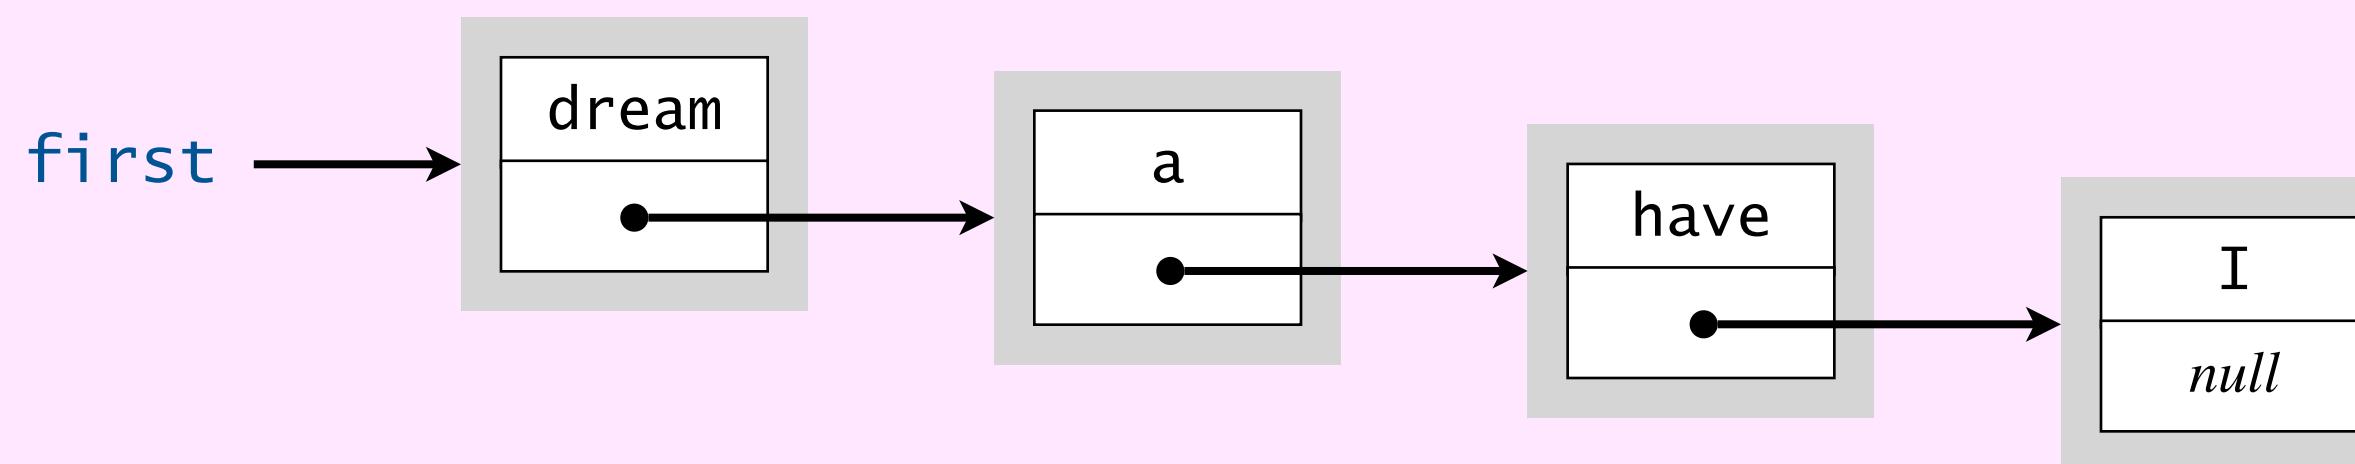

Node

# Possible memory representation

Each **Node** object stores a **String** and a reference to the next **Node** in the linked list.

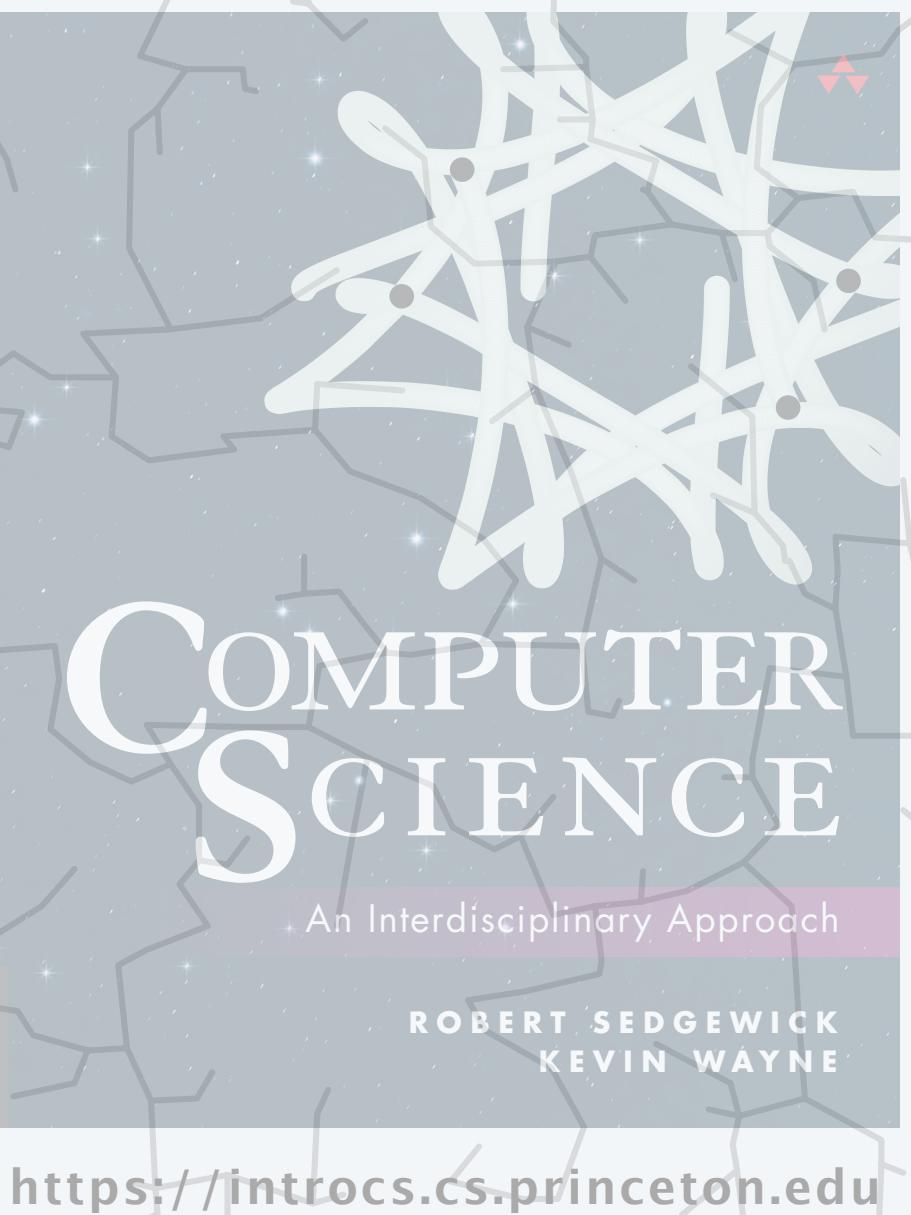

*actually, a reference to a String  
(poetic license)*

# Stack implementation with a linked list

```
public class StackOfStrings {           ← for simplicity, we assume items are of type String  
    private Node first;  
  
    private class Node {  
        private String item;  
        private Node next;  
    }  
  
    public class Stack() {  
        first = null;  
    }  
  
    public void push(String item) {  
        Node oldFirst = first;  
        first = new Node(); ← no Node constructor explicitly defined ⇒ Java supplies default no-argument constructor  
        first.item = item;  
        first.next = oldFirst;  
    }  
  
    public String pop() {  
        String item = first.item;  
        first = first.next;  
        return item;  
    }  
}
```

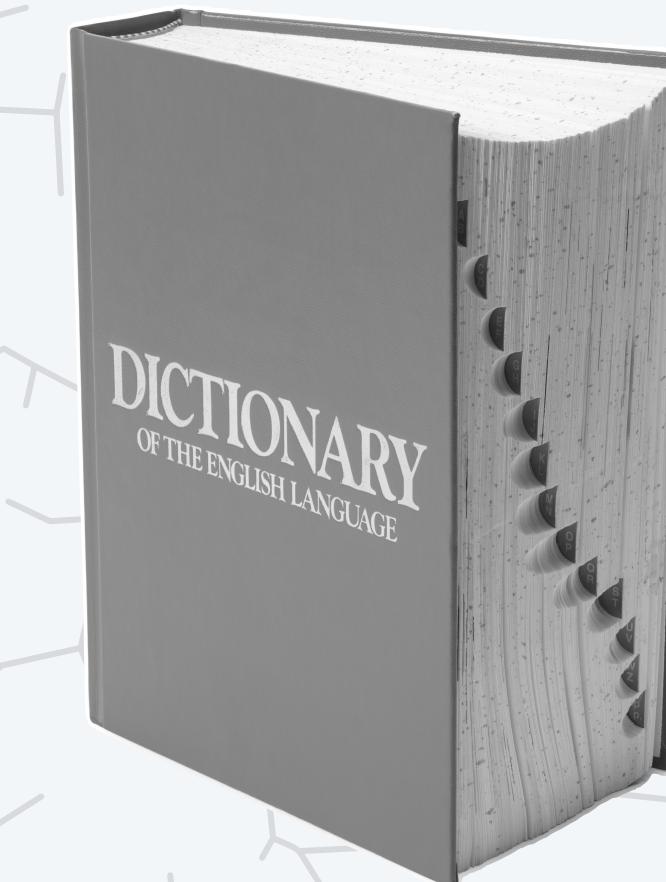

**⚠ code just beyond scope of COS 126**

## 4.3 DATA STRUCTURES

---

- ▶ *collections*
- ▶ *stacks and queues*
- ▶ *linked lists*
- ▶ ***symbol tables***
- ▶ *Java collections framework*

# Symbol tables

---

## Key-value pair abstraction.

- **Insert** a value with specified key.
- Given a key, **search** for the corresponding value.

*also known as maps (Java),  
dictionaries (Python),  
and associative arrays (Perl)*

## Ex. DNS lookup.

- Insert domain name with specified IP address.
- Given domain name, find corresponding IP address.

domain name	IP address
www.cs.princeton.edu	128.112.136.61
goprinctontigers.com	67.192.28.17
wikipedia.com	208.80.153.232
google.com	172.217.11.46

↑  
*key*

↑  
*value*

# Symbol table applications

---

application	purpose of search	key	value
<b>dictionary</b>	<i>find definition</i>	word	definition
<b>compiler</b>	<i>find properties of a variable</i>	variable name	type and value
<b>DNS</b>	<i>find IP address</i>	domain name	IP address
<b>reverse DNS</b>	<i>find domain name</i>	IP address	domain name
<b>file system</b>	<i>find file on disk</i>	filename	location on disk
<b>file share</b>	<i>find song to download</i>	name of song	computer ID
<b>web search</b>	<i>find relevant web pages</i>	keyword	list of page names

Symbol table data type. Our textbook data type for symbol tables.

		Key type must be comparable (String, Integer, Double, ...)
<code>public class ST&lt;Key, Value&gt;</code>		<b>description</b>
<code>ST()</code>	<i>create an empty symbol table</i>	<i>generalizes arrays</i> (keys need not be integers between 0 and $n-1$ )
<code>void put(Key key, Value val)</code>	<i>insert key-value pair</i>	$\leftarrow a[key] = val;$
<code>Value get(Key key)</code>	<i>value paired with key</i>	$\leftarrow a[key]$
<code>boolean contains(Key key)</code>	<i>is there a value paired with key?</i>	
<code>Iterable&lt;Key&gt; keys()</code>	<i>all the keys in the symbol table</i>	
<code>boolean isEmpty()</code>	<i>is the symbol table empty?</i>	
<code>int size()</code>	<i>number of key-value pairs</i>	
⋮		

Performance requirements. `put()`, `get()`, `remove()`, and `contains()` take logarithmic time.

## What does the following code fragment print?

- A. 1.0
- B. 1.5
- C. 2.5
- D. Run-time exception.

```
ST<String, Double> st = new ST<String, Double>();  
st.put("a", 1.0);  
st.put("b", 1.5);  
st.put("a", st.get("a") + st.get("b"));  
double value = st.get("a");  
StdOut.println(value);
```

# Text-to-English

**Goal.** Convert text message with emojis (or text abbreviations) to English.

- Create symbol table that maps from emoji (or text abbreviation) to English.
- Read lines from standard input, replacing emojis (or text abbreviations) with expansions.

## Text-to-English converter: build symbol table

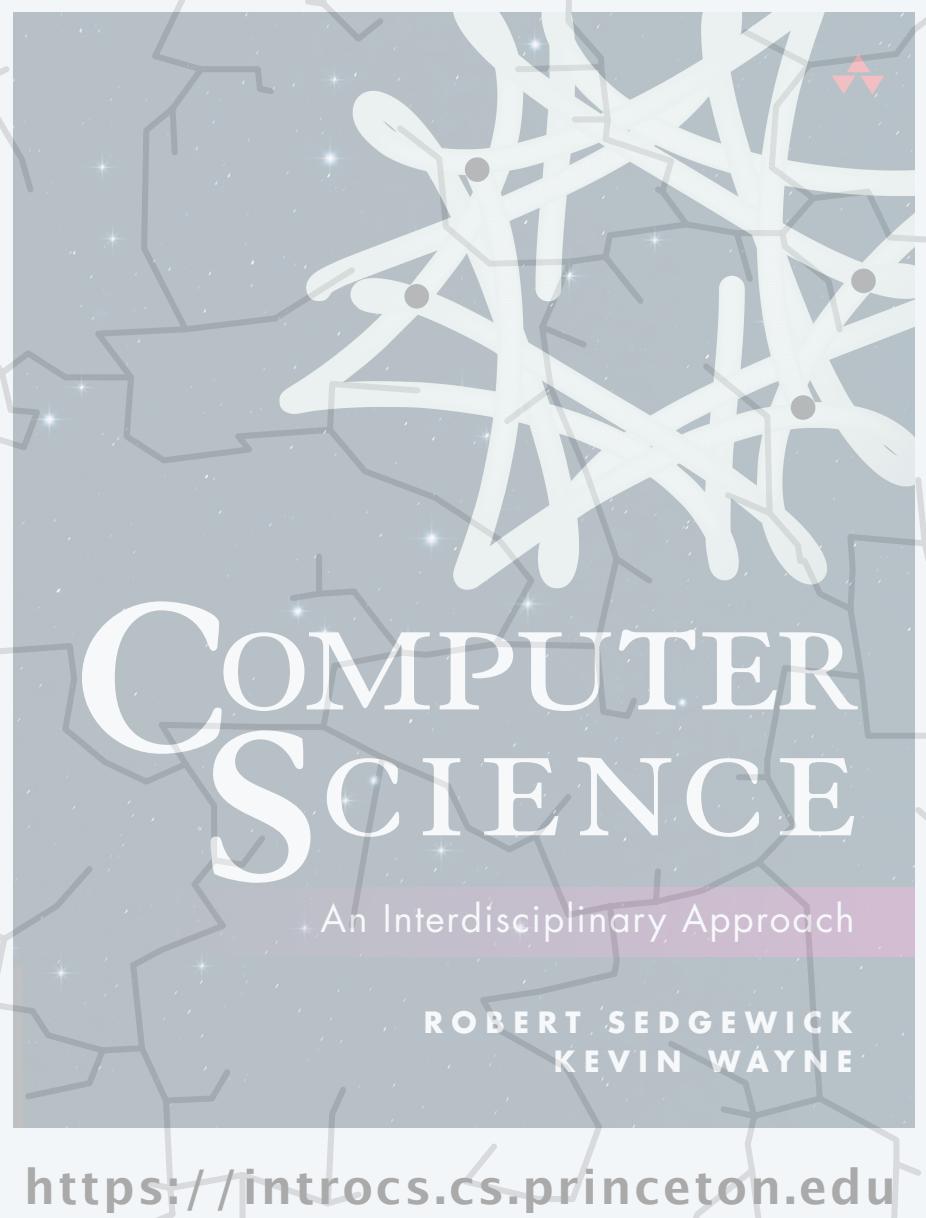

```
public class TextToEnglish {  
    public static void main(String[] args) {  
  
        // build symbol table that maps from abbreviation to expansion  
        ST<String, String> st = new ST<String, String>(); ← create symbol table with  
        In in = new In(args[0]); string keys (abbreviations)  
        while (in.hasNextLine()) {  
            String line = in.readLine();  
            String[] fields = line.split("\t"); ← split line into fields  
            String abbreviation = fields[0]; (using tab as delimiter)  
            String expansion = fields[1];  
            st.put(abbreviation, expansion);  
        }  
  
        ...  
    }  
}
```

*create symbol table with  
string keys (abbreviations)  
and string values (expansions)*

## Text-to-English converter: process lines of text

---

```
public class TextToEnglish {  
    public static void main(String[] args) {  
  
        ...  
  
        // process lines of text, replacing abbreviations with expansions  
        while (StdIn.hasNextLine()) {  
            String line = StdIn.readLine();  
            String[] words = line.split(" "); ← split line into words  
            for (int i = 0; i < words.length; i++) {  
                StdOut.print(words[i] + " ");  
                if (st.contains(words[i])) {  
                    StdOut.print("[" + st.get(words[i]) + "] " + " "); ← print expansion  
if word is in symbol table  
(delimiting with square braces)  
                }  
            }  
            StdOut.println();  
        }  
    }  
}
```

## 4.3 DATA STRUCTURES

---

- ▶ *collections*
- ▶ *stacks and queues*
- ▶ *linked lists*
- ▶ *symbol tables*
- ▶ ***Java collections framework***

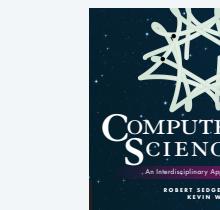

# System libraries

Textbook libraries. Collections for stacks, queues, symbol tables, sets, ...

Java collections framework. Collections for lists, symbol tables (maps), sets, ...

collection	core operations	introcs.jar	java.util
<i>stack</i>	PUSH, POP	Stack	<del>java.util.Stack</del> java.util.LinkedList ← <i>provides superset of stack/queue operations</i>
<i>queue</i>	ENQUEUE, DEQUEUE	Queue	java.util.ArrayList
<i>symbol table</i>	PUT, GET, DELETE	ST	java.util.TreeMap java.util.HashMap
<i>set</i>	ADD, CONTAINS, DELETE	SET	java.util.TreeSet java.util.HashSet
:	:	:	

## Java collections framework: lists

`java.util.LinkedList`. Java collections framework data type for lists.

<code>public class LinkedList&lt;Item&gt;</code>		<b>description</b>	<b>running time (worst case)</b>
	<code>LinkedList()</code>	<i>create an empty list</i>	$\Theta(1)$
<code>void</code>	<code>addFirst(Item item)</code>	<i>add a new item to the beginning of list</i>	$\Theta(1)$
<code>void</code>	<code>addLast(Item item)</code>	<i>add a new item to the end of list</i>	$\Theta(1)$
<code>Item</code>	<code>removeFirst()</code>	<i>remove and return item at beginning of list</i>	$\Theta(1)$
<code>Item</code>	<code>removeLast()</code>	<i>remove and return item at end of list</i>	$\Theta(1)$
<code>boolean</code>	<code>isEmpty()</code>	<i>is the list empty?</i>	$\Theta(1)$
<code>int</code>	<code>size()</code>	<i>number of items in the list</i>	$\Theta(1)$
<code>Item</code>	<code>get(int index)</code>	<i>return item at specified position in list</i>	$\Theta(n)$
<code>:</code>			

Performance requirements. “Core” operations take constant time.  *but many other LinkedList operations do not (!)*

## Java collections framework: symbol tables

`java.util.TreeMap`. Java collections framework data type for symbol tables (maps).

<code>public class TreeMap&lt;Key, Value&gt;</code>	<b>description</b>	<b>running time (worst case)</b>	
<code>TreeMap()</code>	<i>create an empty symbol table</i>	$\Theta(1)$	
<code>Value put(Key key, Value val)</code>	<i>insert key–value pair</i>	$\Theta(\log n)$	
<code>Value get(Key key)</code>	<i>value paired with key</i>	$\Theta(\log n)$	
<code>boolean containsKey(Key key)</code>	<i>is there a value paired with key?</i>	$\Theta(\log n)$	← <i>similar to API for ST</i>
<code>void remove(Key key)</code>	<i>remove key (and associated value)</i>	$\Theta(\log n)$	
<code>Set&lt;Key&gt; keySet()</code>	<i>all the keys in the symbol table</i>	$\Theta(n)$	
<code>boolean isEmpty()</code>	<i>is the symbol table empty?</i>	$\Theta(1)$	
<code>int size()</code>	<i>number of key–value pairs</i>	$\Theta(1)$	
<code>:</code>			

**Performance requirements.** “Core” operations take logarithmic time.

# Enhanced for loop (foreach loop)

Enhanced for loop. A second form of **for** loop designed to iterate over collections (and arrays).

```
LinkedList<String> list = new LinkedList<String>();
list.addLast("I");
list.addLast("have");
list.addLast("a");
list.addLast("dream");

for (String s : list) { ← iterates over list
elements in list order
    StdOut.println(s);
}
```

enhanced for loop with a `java.util.LinkedList`

```
TreeMap<String, Double> map = new TreeMap<String, Double>();
map.put("Hydrogen", 1.01);
map.put("Helium", 4.00);
map.put("Lithium", 6.94);
...
for (String s : map.keySet()) { ← iterates over symbol table
keys in sorted order
    StdOut.println(s + " " + map.get(s));
}
```

enhanced for loop with a `java.util.TreeMap`

```
double[] values = { 0.0, 2.0, 3.0, 6.125, 4.5 };
double sum = 0.0;
for (double x : values) { ← iterates over array
elements in array order
    sum += x;
}
```

enhanced for loop with an array

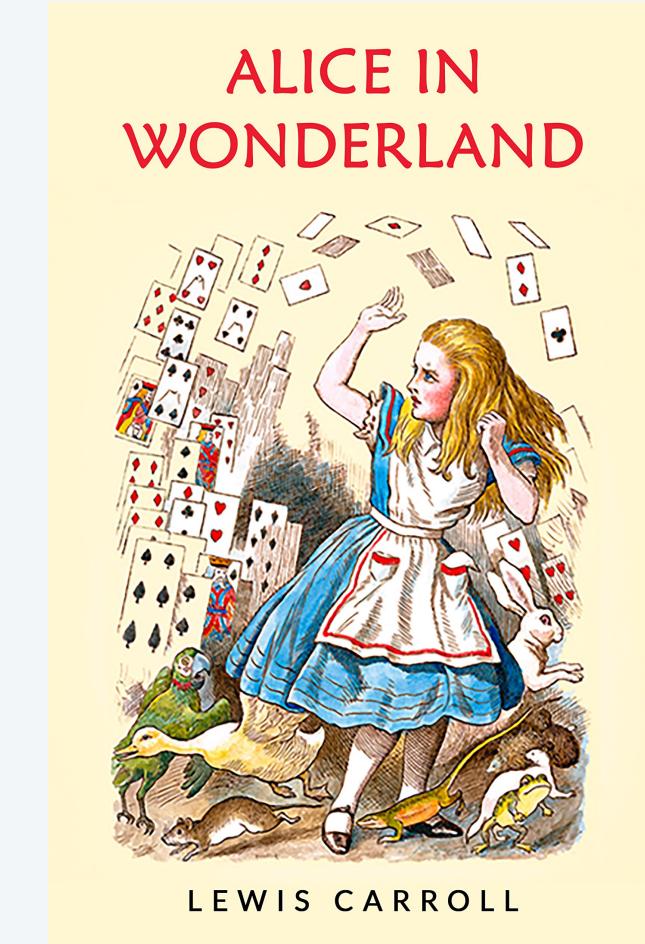

# Concordance

A **concordance** is a list of every occurrence of each word in a text, along with surrounding context.

indices where  
query word  
appears →

```
~/Desktop/ds> java-introcs Concordance alice.txt 5 ← context window radius
hole ← query word
12: chapter i down the rabbit hole alice was beginning to get
266: pop down a large rabbit hole under the hedge in another
293: get out again the rabbit hole went straight on like a
1267: much larger than a rat hole she knelt down and looked
6809: hadn't gone down that rabbit hole and yet and yet it's
      ← context window →
flamingo
17067: first was in managing her flamingo she succeeded in getting its
17458: then alice put down her flamingo and began an account of
17931: only difficulty was that her flamingo was gone across to the
17967: time she had caught the flamingo and brought it back the
18768: about the temper of your flamingo shall i try the experiment

hippopotamus
3567: must be a walrus or hippopotamus but then she remembered how
```

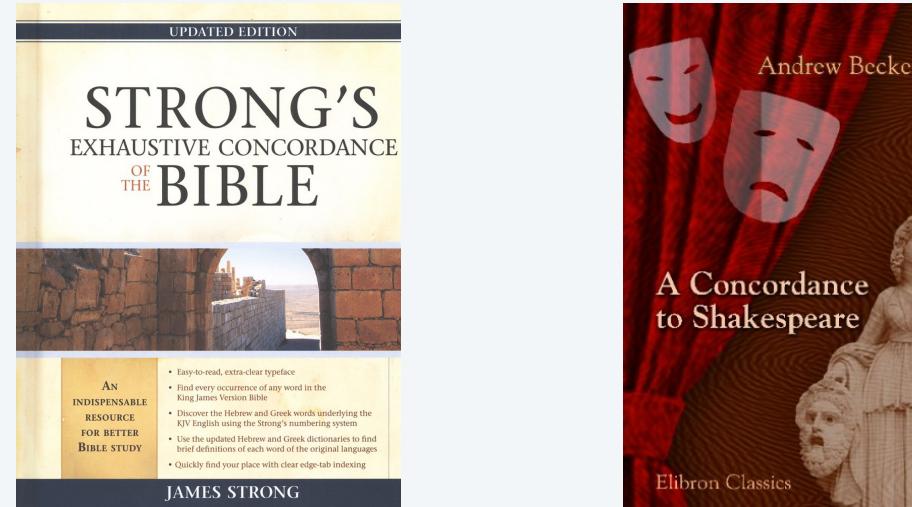

# Concordance

---

A **concordance** is a list of every occurrence of each word in a text, along with surrounding context.

Pre-computational age. Compiled only for works of special importance:

- Vedas.
- Bible.
- Qur'an.
- Works of Shakespeare.
- ...

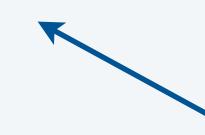

Computational age. Any COS 126 student can create one!

Spotlight search (iOS or OS X). Essentially a concordance of files on your phone/computer.

Google search. Essentially a concordance of the web.

*with clever algorithm  
to rank results*

**What should the declared type be for a symbol table for concordance?**

- A.** `TreeMap<String, Integer>`
- B.** `TreeMap<Integer, String>`
- C.** `TreeMap<String, LinkedList<Integer>>`
- D.** `TreeMap<LinkedList<Integer>, String>`

## Concordance implementation: build concordance

```
import java.util.LinkedList; |———— access Java collections libraries
import java.util.TreeMap;

public class Concordance {
    public static void main(String[] args) {
        In in = new In(args[0]);
        String[] words = in.readAllStrings(); |———— read all words in file

        // build concordance
        TreeMap<String, LinkedList<Integer>> map = new TreeMap<String, LinkedList<Integer>>();
        for (int i = 0; i < words.length; i++) {
            String s = words[i];

            if (!map.containsKey(s)) {
                map.put(s, new LinkedList<Integer>()); |———— first occurrence of word
            }

            LinkedList<Integer> list = map.get(s); |———— get list associated with word
            list.addLast(i); |———— add index of word to list
        }

        :
    }
}
```

## Concordance implementation: process queries

```
public class Concordance {  
    public static void main(String[] args) {  
        :  
  
        int context = Integer.parseInt(args[1]); ← context window radius  
  
        // process queries  
        while (!StdIn.isEmpty()) {  
            String query = StdIn.readString();  
            if (map.containsKey(query)) {  
                LinkedList<Integer> list = map.get(query);  
                for (int k : list) {  
                    int start = Math.max(k - context, 0);  
                    int end = Math.min(k + context, words.length - 1);  
                    for (int i = start; i <= end; i++) {  
                        StdOut.print(words[i] + " ");  
                    }  
                    StdOut.println();  
                }  
            }  
        }  
    }  
}
```

*list of indices where word appears*

*print 5 words before and after (context window)*

# Collections summary

---

## Fundamental data types.

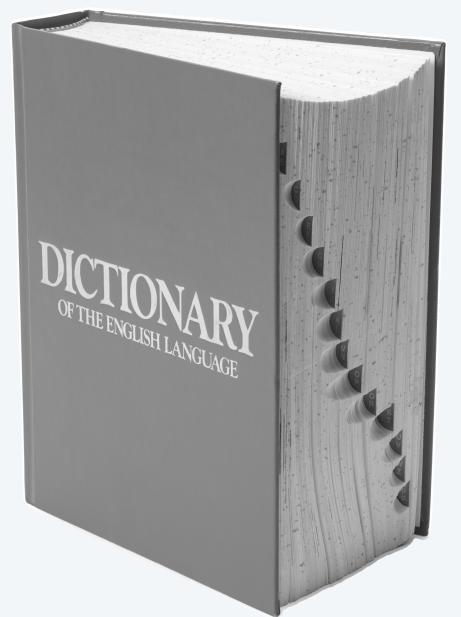

- Value: **collection** of objects.
- Operations: **add**, **remove**, **iterate**, **size**, ...

**Stack.** Remove the item most recently added.

**Queue.** Remove the item least recently added.

**Symbol table.** Associate key-value pairs.

...

**COS 126.** Use pre-existing collection data types.

**COS 226.** Implement your own collections using **linked data structures** and **resizing arrays**.
