Software Project Management

The art of herding cats

Some sobering stats

- 42% of technology projects are abandoned before completion
- >50% of completed projects exceed cost/time budgets by 150% or more
- 17% get solid business sponsorship

Source: Computer World, 3/22 p. 32

Why?

- Business failures
 - Poorly conceived ideas
 - Lack of real sponsorship
 - Unrealistic goals & schedules
- Technologists failures
 - Unrealistic or vague schedules
 - Failure to monitor & react appropriately
 - Just plain old bad designs

Successful projects

- Align business people & technologists
 - Engaged business leadership is essential
 - Increasingly, technologists *must* be business-savvy
- Establish climate of realism
 - What's doable
 - What's essential
- Tracking, tracking, tracking

Milestones this week

DATE	TEAM	MILESTONE
9-Apr 9-Apr 10-Apr 11-Apr 9-Apr 9-Apr 12-Apr 12-Apr 12-Apr 15-Apr 16-Apr	Seige sound images redemption PIM At5000 trading system clipbook space dust campus cal. vulcan logic studio pacman 2000	minimum implementation complete create visual frames for 1 sec. Music at 20 fps menu interface, mostly complete animation engine publishing debugged, UI for new projects complete functionality complete market clearing, 3 strategies & basic investor interfactile I/O & mostly completed GUI sound effects & wrapping pers'lized email, visualization & initial pers'lization graphical game display basic timing in evaluator, graphic input usable game & main classes, 2nd ghost, keyboard input
17-Apr	direct chat	dynamic IP server complete

Are you there?

- How do you know?
 - A good milestone is concrete
 - A better one is demonstrable
- Be wary of undue optimism

If you're not done, why not?

- Harder than estimated
- More distractions
- Unplanned dependencies had to be done first
- Got behind early and stayed behind

What's the plan, now?

- Work harder....(popular but rarely works)
- Doesn't matter, you built in slack
- Rebalance work within the team
- Change definition of what's to be delivered

Milestones next week

	DATE	TEAM	MILESTONE
23-Apr pacman 2000 ready for integration 23-Apr Seige test for components complete 23-Apr trading system market condition testing complete 24-Apr redemption collision dection, most of combat prototype works perfectly w/ real data	21-Apr 23-Apr 23-Apr 23-Apr 23-Apr 24-Apr 25-Apr 25-Apr 26-Apr 30-Apr 1-May	direct chat logic studio pacman 2000 Seige trading system redemption sound images PIM campus cal. vulcan space dust	ready for integration test for components complete market condition testing complete collision dection, most of combat prototype works perfectly w/ real data simple C/S interaction complete & tested multiple keyword & pattern search networking & multple game/chat project presentable

Are you still ok?

- Is it time to start on the extras?
- Did you just barely make this week's deliverables and next week is hopeless
 - Looking out a week or two is often a good mechanism for checking optimism

What do project managers do?

- Nominally
 - Plan
 - Organize
 - Monitor
 - Control
- Really
 - Communicate, communicate, communicate
 - Remove excuses for failure

Planning

- Project definition
 - Negotiate features with customers
 - Ascertain doability & any assets available
 - Understand risk profile
- Staffing and other needs
- Rough cut architecture & schedule
 - Unless you're careful, this schedule will be the schedule

Feature definition

- Minimally
 - High level list of features
 - Rough functional spec for the project
 - Rough priority list for features
- Complex projects need requirements that are trackable
- All projects need unambiguous feature definitions

Doability

- How novel is the project, generally?
- Have you or your team done a similar project before?
- How much of the project can you reuse/purchase?
- How good are your resources (people, computing facilities, tools, office space etc.)?

Risk profile

- What happens if you fail?
- What constitutes failure?
 - Schedule?
 - Cost?
 - Features?
 - Which one(s)?
- Will this project get to commandeer resources or be a source for others?

Staffing & resources

- Who (individuals or expertise) do you need?
 - Requirements, development, test
- Are the right people on staff already?
- Are the skills you need hard to find?
- Do you have the right & enough computing facilities including development and test tools?

Initial schedule

- Often, the schedule is dictated
- Until you really know what you're doing try not to commit to dates
 - Intervals are often acceptable at this stage
- Always qualify any schedule to indicate confidence

Thoughts on schedules

- Schedule, cost, features. Pick any two.
 - Most projects are constrained on all three.
 - Most projects fail.....
- Don't kid yourself
- Consider 2 sets of books, padding the external schedule by at least 20%
- Learn how to communicate constraints effectively

Organize

- Get the right people and tools
- Assign tasks to teams/individuals
- Establish reporting structure
 - Who tracks progress
 - How often
 - What mechanism (meetings, email, paper)
- Establish other project processes

Team structures

- Individuals almost always specialize
 - By kind of work (requirements, test etc.)
 - By functional area (UI, DB, various application domains etc.)
- Teams are composed of individuals
- Teams are charged with some goal

Kinds of teams

- Functional teams are organized by their specialties and tend to persist
- Feature teams form and reform to accomplish a specific task
- A hybrid approach is feature teams matrixed from functional team members

Functional teams

- Do best when the project area is very complex and requires a high degree of personal depth
 - Tend to be used by more mature projects
- Can result in people aligning with their specialty instead with the overall goals

Feature teams

- Do best in responding to rapid change
 Tend to be used when things are new
- Can result in team members letting their expertise languish—the needs of the team outweigh the needs of individuals to keep current

Hybrid teams

- Can have either the advantages or disadvantages of both
- They are harder to manage and require a substantial commitment from management and staff to work well
- When they work well, they can be the most effective approach

Minimal project processes

- Feature definitions
- Architecture control
- Change control
- Source control
- Schedule creating and tracking
- Testing
- Trouble tracking

Architecture

- Surprisingly few projects do this well
- It's more than a picture
- Essentials
 - Interfaces, including specification of how data/control will cross interface boundaries
 - Hardware & software components
 - Software guidelines

Change control

- Most essential for identifying new requirements
 - New feature requests
 - Features masquerading as bug reports
 - Features generated by the team itself
- Usually requires some kind of record keeping and periodic review

Change control process

- Must ensure
 - Changes are identified
 - Conscious decisions are made on cost/benefit of the change
 - Impacts of any change are understood and planned for
 - Changes are communicated to those who need to know

Monitor

- How do you know you're on target?
 - Right features being built
 - On schedule
 - On budget
- Pay special attention to risks and high priority features
- Too much and too little are both bad

Schedules

- Measurable milestones
 - Start, original and current end dates
 - Dependencies
 - Owner
- Rule of thumb: Milestones should be no more than 2-weeks apart
 - Internet projects should apply normal "internet time" factor and divide by 4 (i.e. every couple of days)

Intermediate deliverables

- Plan check-points where things are working and you can use the system
- Show what you've got to your customers
- As the project manager, use the system yourself and judge how good is it really

Testing

- Early and often
 - Test progress is the best way to know what you've got and counter optimism
- Test development should begin no later than when development starts
- Weekly builds when more than 2 months from delivery, daily thereafter

Meetings....

- A necessary evil
- Remember both parts
 - Necessary: Without them it's too hard to know what's going on or to communicate to the team what they need to know
 - Evil: It's easy to let meetings drone on and accomplish little

Effective meetings

- Start on time
- Have an agenda with a strict end-time
- Have an owner who drives the meeting to achieve its objectives within the allotted time
- Have minutes published within a day and disseminated widely

Reasonable meetings

- Monthly all-hands meetings to discuss project goals and high-level status
- Weekly team meetings to review milestones & open issues
- Weekly management meetings to track overall progress & issues
- Periodic meetings with nondevelopment partners

Daily status meetings

- Only when the project nears completion
- Objective to identify any issues that may delay completion
- To be effective:
 - Issues must close quickly
 - Must be short (15 45 minutes)
- Attendance is a good indicator of whether the meetings are working

Control

- Stuff happens
- Control is what you do about it

Effective control

- Depends on
 - Risk analysis/priorities defined during planning
 - Early warning given from monitoring systems
- Waiting to act usually makes the solution worse, not better

Options

- Add resources
 - Often, adding resources to a late project makes it later, but sometimes this works
- Redefine the deliverable
 - Drop features
 - Relax schedule constraint
 - Reduce quality (this one usually just delays the problem)

Wrap up

- Good project management is hard
- The essence:
 - Know what's important
 - Know what's happening
 - Do something about it
