

# Object Recognition: the Case for 2D Multiple Views

C. Andrew Burlingame

COS594B: Vision

February 25, 2008

# Elegant Geons Don't Fit the Data

- Geon model predicts no systematic affect of viewpoint.
- Reaction time (RT) and error rates (ER) both affected by viewpoint for certain object types.

CANONICAL

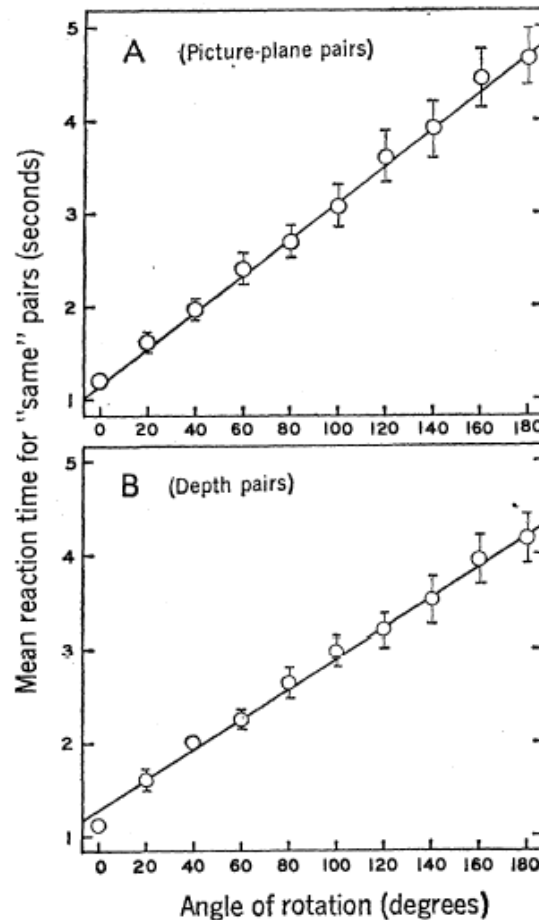

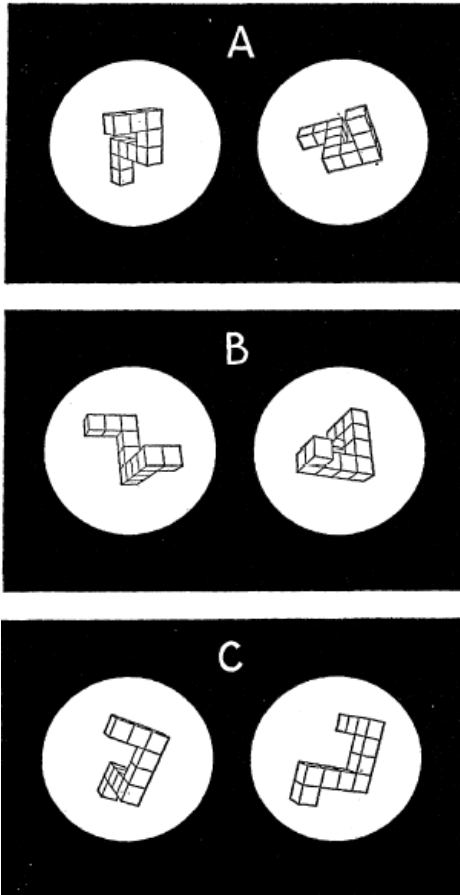

NON-CANONICAL

# Inconsistent Results

- Little effect of viewpoint for very familiar objects
- Definite effect for novel objects
  - Effect decays with familiarity
- Explanation:
  - Handedness or “top/bottom” must be determined
  - View-invariant model built over time
  - Multiple-view model elaborated with time

# Rotation for Handedness

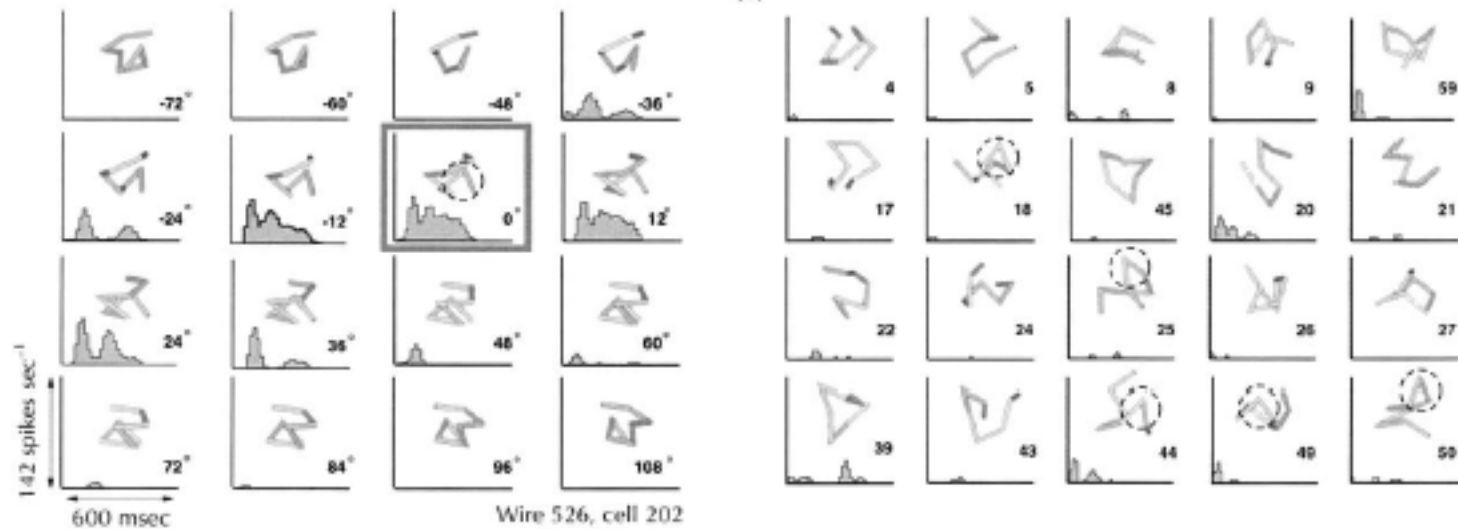

- Object must be rotated to “upright” to compare right and left.
- Normalization only necessary in handedness determination.
- Non-ethological studies.
- Surreptitious check for handedness.

Shepard and Metzler, 1971

- Handedness determination established to involve angle-dependent normalization: “mental rotation.”

# Electrophysiological Aside

(b)

# Tarr's Response

Tarr, 1995

- Goals:
  - Explicitly eliminate handedness from study.
  - Establish same normalization procedure used for handedness determination and object identification
- Problems:
  - Do these objects have geons?

- Clearly defined base
- Subjects built and named objects
  - In both versions
  - Doing their best to allow for 3D model development

# Tarr's Response

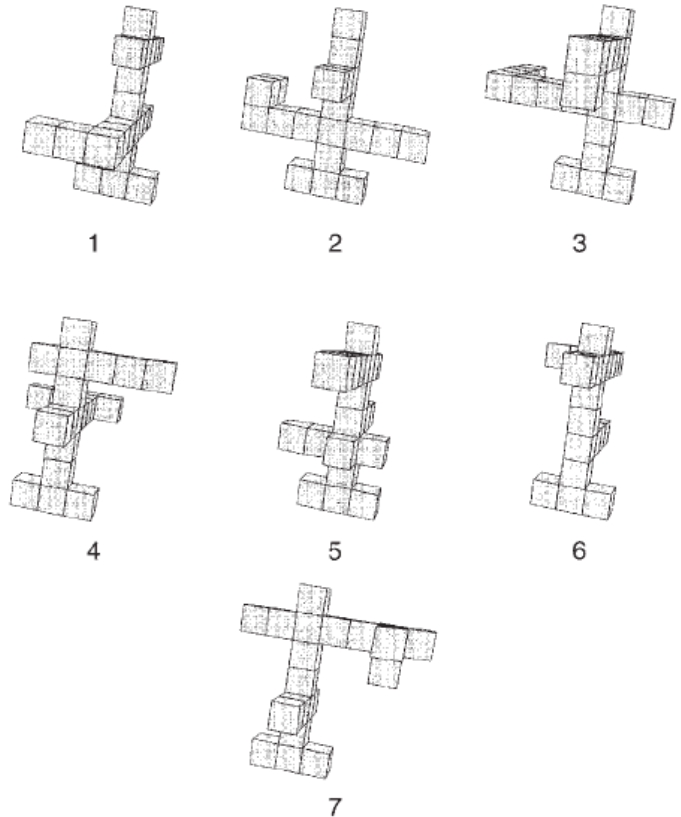

Tarr, 1995

- General scheme of experiments
  - **Train:** Subset of test images shown on a specific orientation ( $10^\circ$  off each axis)
  - **Practice:** Subset of test images shown at an additional orientation ( $130^\circ$  off axis)
    - Set's “multiple-view”
  - **Test:** Images (often containing distracters) shown at a variety of viewpoints

# Tarr's Baseline:

## Establish Mental Rotation Effects

- Handedness Task
- Kip, Kef, Kor
- **Train:**  $10^\circ$  off each axis
- **Practice:** add  $130^\circ$  off axis

# Tarr's Baseline:

## Establish Correlates of Rotation

- **Test:** 11 viewpoints at 30° intervals about each axis
- **Results:**
  - May be explained by Rotation for Handedness
  - Shortest path rotation (usually)
  - Multiple View
  - Interpolation vs. Extrapolation

# Tarr's Correlate:

## Compare Rotation to Identification

- Identification Task
- Inverted objects did not appear
- Presence of Distracters
- Similarity to Exp 1 suggests same mechanism used in identification as handedness
- Failed to find any effects of visible feature set
  - Subjective evaluation of foreshortening

# Tarr and Pinker, 1989

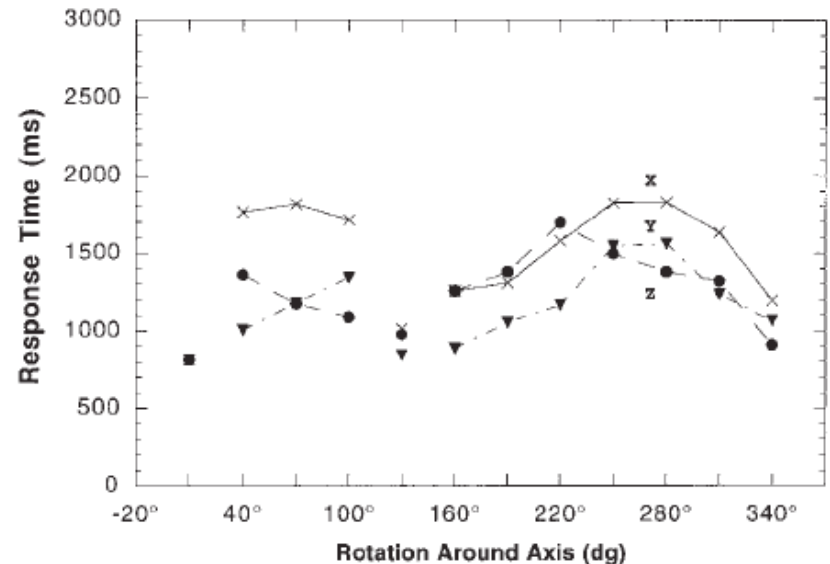

## A Very Odd Result

- 2D Objects
- Handedness explicitly irrelevant
  - Subjects trained on both orientations
  - Mirror pairs assigned same name
- Response time flat for all reversed images!
  - 180° rotation will always align
- With training in both orientations
  - Viewpoint variability recovered
- However, mirror image effects seen as evidence of invariant model

# Tarr's Invisible Hand:

## Handedness Explicitly Removed

- Suppose models are invariant to viewpoint *and* handedness.
- Subjects may be “surreptitiously” determining handedness
- For 3D objects, rotation alignment would have to be in 4D.
- Two versions:
  - Learned both versions
  - Learned only standard version

- In both cases, images appear to have been normalized to the nearest learned orientation.
  - Even if that learned orientation was of a different handedness.

# Bülthoff, Edelman, & Tarr, 1994

The Alpha and Omega, Now with Sprinkles!

## Canonical Views

Some viewpoints are better than others.

Magnitude of this effect tends to decay with time

Monkeys and faces

View-sphere visualization of  $RT = f(\text{viewangle})$   
Session 1

Session 2

# Electrophysiological Aside

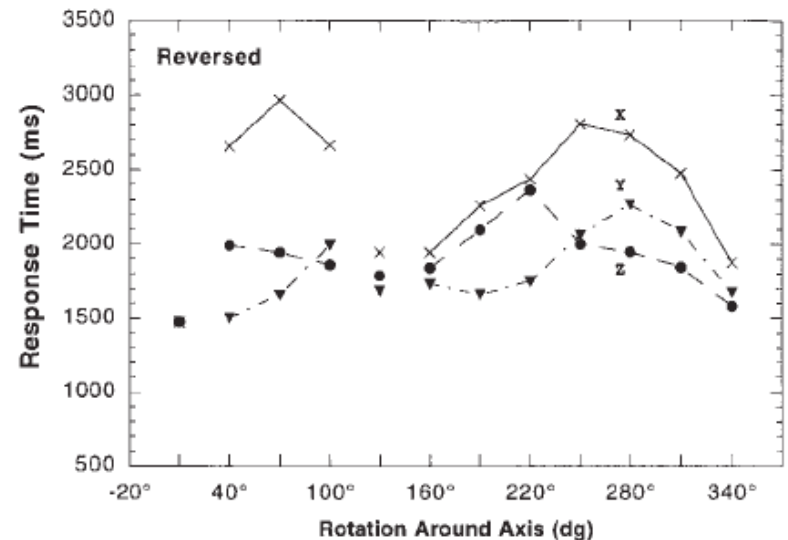

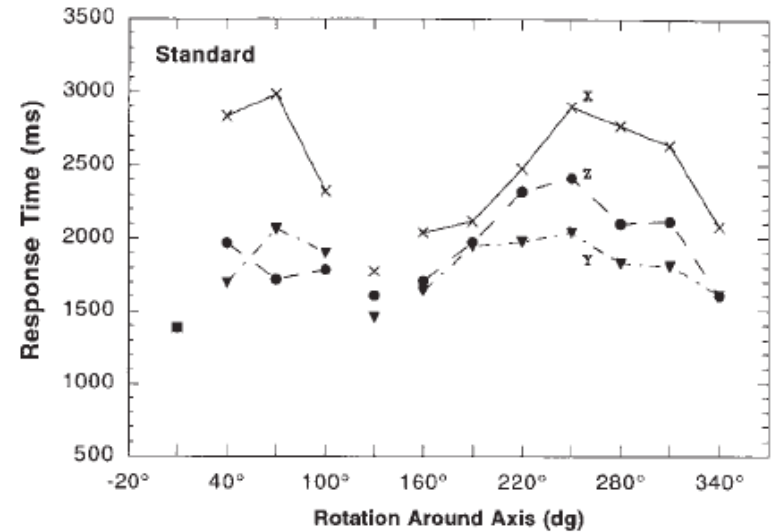

Neural correlates of model development

(c)

# In the Familiar Limit: Heavy Viewing

- Inverted images not shown until test phase.
- Inverted objects shown to be normalized to nearest familiar orientation.
- Evidence of handedness-invariant multiple-view model?

# Object Models with Practice

- Given identification of familiar objects seems viewpoint independent
  - Does this imply development of an independent model?
  - Let's practice

Human Subjects

# Comparison with Models

- Clearly some form of normalization is not only extant but systematic.
- Is psychophysical data consistent with any particular normalization model?
- Ullman's Method of Alignment: (Ullman, 1989)
  - A small number of orientation features used to align an object
  - Projection to 2D and comparison.
  - Expected Results:
    - Variable reaction time
    - Constant error rate

# Comparison with Models

- Linear Combination of Views
  - Ullman and Basri, 1991
  - Any object point can be represented as a linear combination of the points of the same feature in a small number of 2D sample image representations.
  - Object is recognized if the test image lies in the subspace spanned by the “basis” views.
  - Expected results
    - Invariance in the subspace spanned by training views.

# Comparison with Models

- HyperBF

- Poggio and Edelman, 1990; Poggio and Girosi, 1990)
- Output by threshold.
- Most consistent with psychophysical data.
  - Somewhat complex performance variability

$$f(\vec{x}) = \sum_{\alpha=1}^K c_{\alpha} G(\|\vec{x} - \vec{t}_{\alpha}\|)$$

# Synthesis:

Foster and Gilson, 2002

- Same/Different task
- Objects defined by normalized:
  - Number of elements
  - Length of elements
  - Curvature of elements
  - Angle of join
- “Different” pairs only varied by one attribute.
- Discriminability:

$$d' = z(HR) - z(FAR)$$

# Results

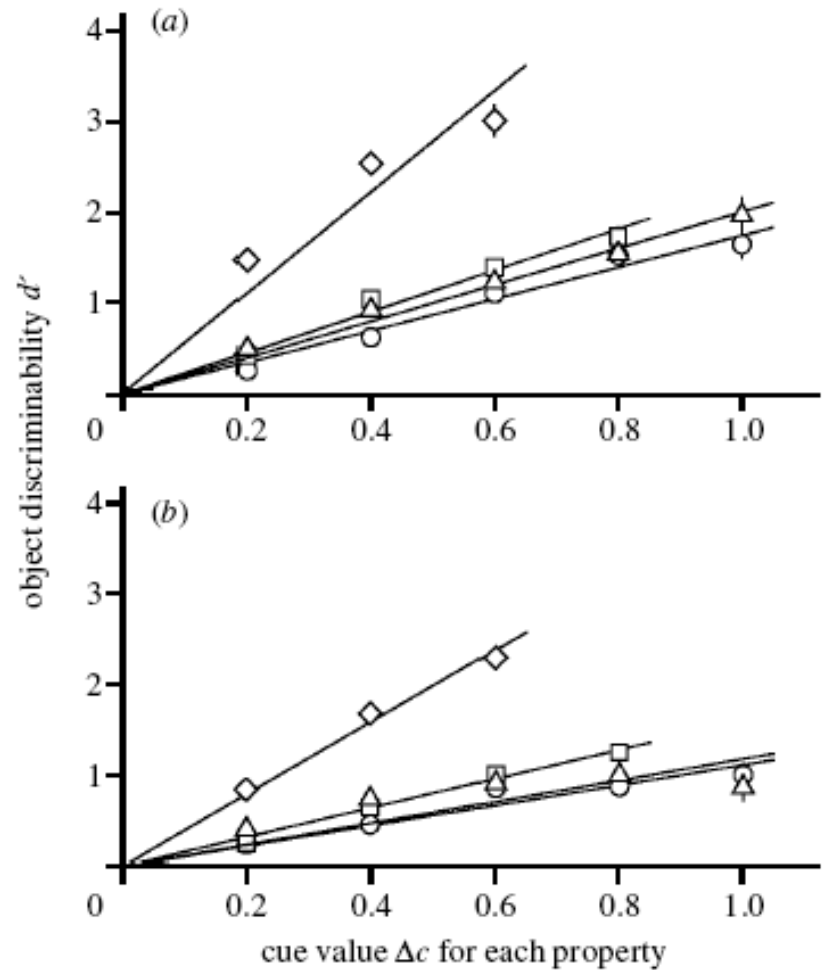

Foster and Gilson, 2002

- Linear dependence of discriminability on cue value

- Additivity of discriminability

$$d' = [k_i + f(\theta)]\Delta c$$

# Summary

- In the end, both sides agree
  - A change in viewpoint will result in viewpoint costs
    - Small in some cases
  - Invariant structural properties important for generalizing across viewpoint
  - Data supporting both sides has been replicated many times
    - Can no longer argue opponent's results are a special case
- Moving on, we try to understand how both types of analysis combine to provide robust object recognition
