What is the computational cost of automating brilliance or serendipity? (Computational complexity and P vs NP question)

COS 116: 4/12/11 Sanjeev Arora

#### **Combination lock**

Why is it secure? (Assume it cannot be picked)

Ans: Combination has 3 numbers 0-39...thief must try  $40^3 = 64,000$  combinations

#### Exponential running time

2<sup>n</sup> time to solve instances of "size" n

Increase n by 1  $\rightarrow$  running time doubles!

Main fact to remember:

For n = 300,  $2^n > number$  of atoms in the visible universe.

#### **Boolean satisfiability**

 $(\mathsf{A} + \mathsf{B} + \mathsf{C}) \cdot (\overline{\mathsf{D}} + \mathsf{F} + \mathsf{G}) \cdot (\overline{\mathsf{A}} + \mathsf{G} + \mathsf{K}) \cdot (\overline{\mathsf{B}} + \mathsf{P} + \mathsf{Z}) \cdot (\mathsf{C} + \overline{\mathsf{U}} + \overline{\mathsf{X}})$ 

- Does it have a satisfying assignment?
- What if instead we had 100 variables?
- 1000 variables?
- How long will it take to determine the assignment?

#### Discussion

Is there an inherent difference between

being creative / brilliant

and

being able to appreciate creativity / brilliance?

What is a computational analogue of this phenomenon?

## A Proposal

#### Brilliance = Ability to find "needle in a haystack"

Beethoven found "satisfying assignments" to our neural circuits for music appreciation

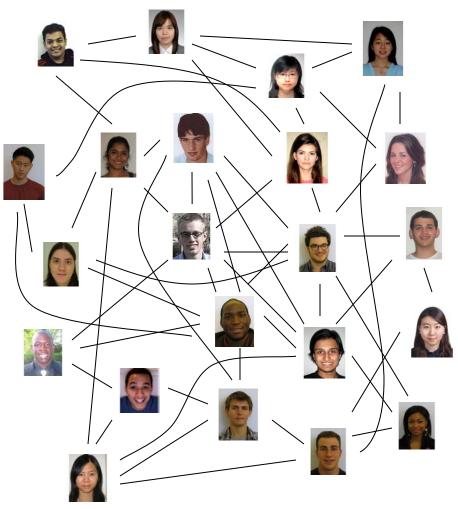

Comments??

There are many computational problems where finding a solution involves "finding a needle in a haystack"....

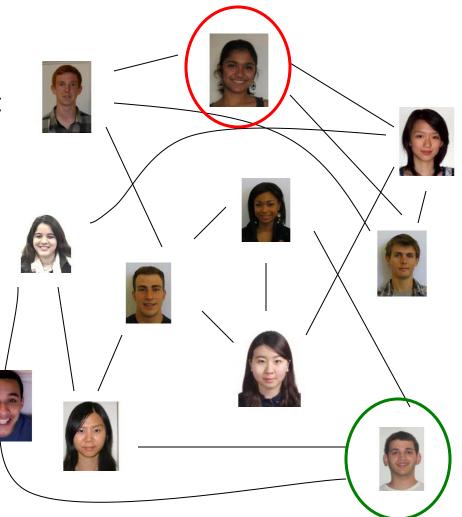

## **CLIQUE** Problem

- In this social network, is there a CLIQUE with 5 or more students?
- CLIQUE: Group of students, every pair of whom are friends
- What is a good algorithm for detecting cliques?
- How does efficiency depend on network size and desired clique size?

## Rumor mill problem

- Social network for COS 116
- Each node represents a student
- Two nodes connected by edge if those students are friends
- Pritha starts a rumor
- Will it reach Benjamin?
- Suggest an algorithm
- How does running time depend on network size?
- Internet servers solve this problem all the time ("traceroute" in Lab 9).

#### Exhaustive Search / Combinatorial Explosion

Naïve algorithms for many "needle in a haystack" tasks involve checking all possible answers → exponential running time.

- Ubiquitous in the computational universe
- Can we design smarter algorithms (as for "Rumor Mill")? Say, n<sup>2</sup> running time.

## Harmonious Dorm Floor

Given: Social network involving n students.

Edges correspond to pairs of students who <u>don't</u> get along.

Decide if there is a set of k students who would make a harmonious group (everybody gets along).

Just the Clique problem in disguise!

# Traveling Salesman Problem (aka UPS Truck problem)

- Input: *n* points and all pairwise inter-point distances, and a distance k
- Decide: is there a path that visits all the points ("salesman tour") whose total length is at most k?

## Finals scheduling

- Input: n students, k classes, enrollment lists, m time slots in which to schedule finals
- Define "conflict": a student is in two classes that have finals in the same time slot
- Decide: if schedule with at most 100 conflicts exists?

#### The P vs NP Question

- P: problems for which solutions can be found in polynomial time (n<sup>c</sup> where c is a fixed integer and n is "input size"). Example: Rumor Mill
- NP: problems where a good solution can be <u>checked</u> in n<sup>c</sup> time. Examples: Boolean Satisfiability, Traveling Salesman, Clique, Finals Scheduling
- Question: Is P = NP?

"Can we automate brilliance?"

(Note: Choice of computational model ---Turing-Post, pseudocode, C++ etc. --- irrelevant.)

#### NP-complete Problems

#### Problems in NP that are "the hardest" If they are in P then so is **every** NP problem.

Examples: Boolean Satisfiability, Traveling Salesman, Clique, Finals Scheduling, 1000s of others

How could we possibly prove these problems are "the hardest"?

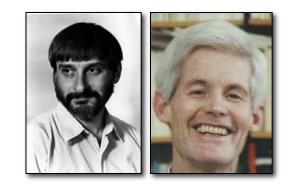

#### "Reduction"

"If you give me a place to stand, I will move the earth." – Archimedes (~ 250BC)

"If you give me a polynomial-time algorithm for Boolean Satisfiability, I will give you a polynomial-time algorithm for every NP problem." --- Cook, Levin (1971)

"Every NP problem is a satisfiability problem in disguise."

#### Dealing with NP-complete problems

- 1. Heuristics (algorithms that produce reasonable solutions in practice)
- 2. Approximation algorithms (compute provably near-optimal solutions)

#### Computational Complexity Theory: Study of Computationally Difficult problems.

A new lens on the world?

- Study matter  $\rightarrow$  look at mass, charge, etc.
- Study processes  $\rightarrow$  look at computational difficulty

## Example 1: Economics

General equilibrium theory:

- Input: n agents, each has some initial endowment (goods, money, etc.) and preference function
- General equilibrium: system of prices such that for every good, demand = supply.
- Equilibrium exists [Arrow-Debreu, 1954].
  Economists assume markets find it ("invisible hand")
- But, <u>no known</u> efficient algorithm to compute it. How does the market compute it?

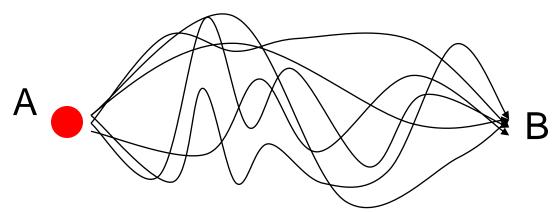

#### Example 2: Factoring problem

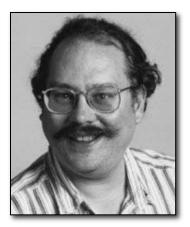

Given a number n, find two numbers p, q (neither of which is 1) such that  $n = p \times q$ .

Any suggestions how to solve it?

Fact: This problem is believed to be hard. It is the basis of much of cryptography. (More next time.)

#### **Example 3: Quantum Computation**

**Peter Shor** 

- Central tenet of quantum mechanics: when a particle goes from A to B, it takes <u>all possible paths all at the same time</u>
- [Shor'97] Can use quantum behavior to efficiently factor integers (and break cryptosystems!)
- Can quantum computers be built, or is quantum mechanics not a correct description of the world?

## **Example 4: Artificial Intelligence**

What is computational complexity of language recognition?

Chess playing?

Etc. etc.

Potential way to show the brain is not a computer: Show it routinely solves some problem that provably takes exponential time on computers.

(Will talk more about AI in a couple weeks)

#### Why is P vs NP a Million-dollar open problem?

 If P = NP then Brilliance becomes routine (best schedule, best route, best design, best math proof, etc...)

 If P ≠ NP then we know something new and fundamental not just about computers but about the world (akin to "Nothing travels faster than light").

## Next time: Cryptography (practical use of computational complexity)
