Data compression

Compression reduces the size of a file:

- To save space when storing it.
- To save time when transmitting it.
- Most files have lots of redundancy.

Who needs compression?

- Moore's law: # transistors on a chip doubles every 18-24 months.
- Parkinson's law: data expands to fill space available.
- Text, images, sound, video, ...

"Everyday, we create 2.5 quintillion bytes of data—so much that 90% of the data in the world today has been created in the last two years alone." — IBM report on big data (2011)

Applications

Generic file compression.

- Files: GZIP, BZIP, 7z.
- Archivers: PKZIP.
- File systems: NTFS, HFS+, ZFS.

Multimedia.

- Images: GIF, JPEG.
- Sound: MP3.
- Video: MPEG, DivX[™], HDTV.

Communication.

- ITU-T T4 Group 3 Fax.
- V.42bis modem.

Databases. Google.

Skype.

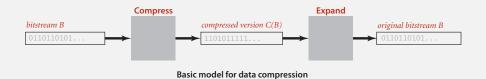

Google

Basic concepts ancient (1950s), best technology recently developed.

Lossless compression and expansion

Message. Binary data B we want to compress. Compress. Generates a "compressed" representation C(B). Expand. Reconstructs original bitstream B.

Compression ratio. Bits in C(B) / bits in B.

Ex. 50-75% or better compression ratio for natural language.

Food for thought

Data compression has been omnipresent since antiquity:

- Number systems.
- Natural languages.
- Mathematical notation.

has played a central role in communications technology,

- Grade 2 Braille.
- Morse code.
- Telephone system.

rechnology.

b	r	а	i	1	1	e
• 0 • 0 0 0 0 0		• 0 0 0 0 0 0 0			● 0 ● 0 ● 0 0 0	
but	rather	a	1	like	like	every

and is part of modern life.

- MP3.
- MPEG.

- Data representation: genomic code
- Genome. String over the alphabet $\{A, C, T, G\}$.
- Goal. Encode an N-character genome: ATAGATGCATAG...

Standard ASCII encoding.

- 8 bits per char.
- 8 *N* bits.

char	hex	binary
A	41	01000001
с	43	01000011
т	54	01010100
G	47	01000111

Two-bit encoding.

- 2 bits per char.
- 2 N bits.

char	binary
A	00
с	01
т	10
G	11

Amazing but true. Initial genomic databases in 1990s did not use such a code! Fixed-length code. k-bit code supports alphabet of size 2^k .

Reading and writing binary data

Q. What role will it play in the future?

Binary standard input and standard output. Libraries to read and write bits from standard input and to standard output.

public c	lass BinaryStdIn	
boolean	readBoolean()	read 1 bit of data and return as a boolean value
char	readChar()	read 8 bits of data and return as a char value
char	readChar(int r)	read r bits of data and return as a char value
[similar m	ethods for byte (8 bits); s	short (16 bits); int (32 bits); long and double (64 bits)]
boolean	isEmpty()	is the bitstream empty?
void	close()	close the bitstream

public class BinaryStdOut

	,	
void	write(boolean b)	write the specified bit
void	write(char c)	write the specified 8-bit char
void	write(char c, int r)	write the r least significant bits of the specified char
[similar me	ethods for byte (8 bits); short	t (16 bits); int (32 bits); long and double (64 bits)]
void	close()	close the bitstream

Date representation. Three different ways to represent 12/31/1999.

00110001001100100010111100110111001100	/ 1 9	0 0	
Three ints (BinaryStdOut)		80 bits	
<pre>BinaryStdOut.write(month); BinaryStdOut.write(day); BinaryStdOut.write(year);</pre>			
000000000000000000000000000000000000000	000000000000000000000000000000000000000	100000000000000000000011111001	111
12	31	1999	96 bits
A 4-bit field, a 5-bit field, and a 12-bit field (E	inarvStdOut)		
A 4-bit field, a 5-bit field, and a 12-bit field (B BinaryStdOut.write(month, 2 BinaryStdOut.write(day, 5); BinaryStdOut.write(year, 12	4); ;		

Q. How to examine the contents of a bitstream?

Binary dumps

Universal data compression

US Patent 5,533,051 on "Methods for Data Compression", which is capable of compression all files.

Slashdot reports of the Zero Space Tuner[™] and BinaryAccelerator[™].

"ZeoSync has announced a breakthrough in data compression that allows for 100:1 lossless compression of random data. If this is true, our bandwidth problems just got a lot smaller...."

Physical analog. Perpetual motion machines.

Gravity engine by Bob Schadewald

Universal data compression

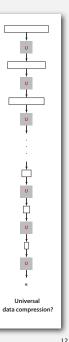

Proposition. No algorithm can compress every bitstring.

Pf 1. [by contradiction]

- Suppose you have a universal data compression algorithm U that can compress every bitstream.
- Given bitstring B₀, compress it to get smaller bitstring B₁.
- Compress B_1 to get a smaller bitstring B_2 .
- Continue until reaching bitstring of size 0.
- Implication: all bitstrings can be compressed to 0 bits!

Pf 2. [by counting]

- Suppose your algorithm that can compress all 1,000-bit strings.
- 2¹⁰⁰⁰ possible bitstrings with 1,000 bits.
- Only $1 + 2 + 4 + ... + 2^{998} + 2^{999}$ can be encoded with ≤ 999 bits.
- Similarly, only 1 in 2^{499} bitstrings can be encoded with ≤ 500 bits!

1000000 bits

A difficult file to compress: one million (pseudo-) random bits

```
public class RandomBits
  public static void main(String[] args)
      int x = 11111;
      for (int i = 0; i < 1000000; i++)</pre>
         x = x * 314159 + 218281;
         BinaryStdOut.write(x > 0);
      }
      BinaryStdOut.close();
   }
}
```

Rdenudcany in Enlgsih Inagugae

Q. How much redundancy is in the English language?

"... randomising letters in the middle of words [has] little or no effect on the ability of skilled readers to understand the text. This is easy to denmtrasote. In a pubiltacion of New Scnieitst you could ramdinose all the letetrs, keipeng the first two and last two the same, and reibadailty would hadrly be aftcfeed. My ansaylis did not come to much beucase the thoery at the time was for shape and senquuce retigcionon. Saberi's work sugsegts we may have some pofrweul palrlael prsooscers at work. The resaon for this is suerly that idnetiyfing coentnt by paarllel prseocsing speeds up regnicoiton. We only need the first and last two letetrs to spot chganes in meniang." - Graham Rawlinson

A. Quite a bit.

13

Run-length encoding

Simple type of redundancy in a bitstream. Long runs of repeated bits.

Representation. Use 4-bit counts to represent alternating runs of 0s and 1s: 15 Os, then 7 1s, then 7 Os, then 11 1s.

1111011101111011 - 16 bits (instead of 40) 15 7 7 11

Q. How many bits to store the counts?

A. We'll use 8.

Q. What to do when run length exceeds max count?

A. If longer than 255, intersperse runs of length 0.

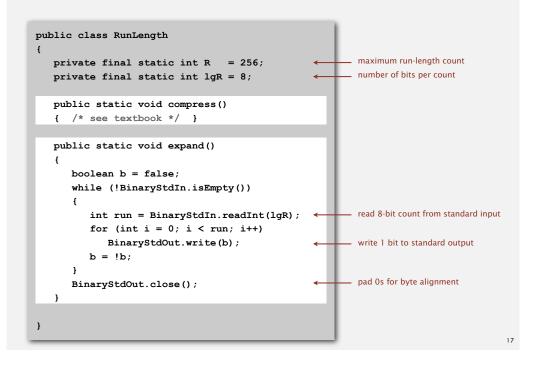

Applications. JPEG, ITU-T T4 Group 3 Fax, ...

15

14

run-length coding

Run-length encoding: Java implementation

An application: compress a bitmap

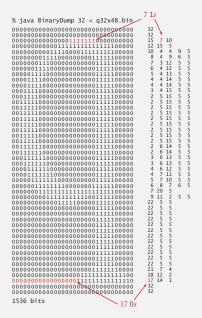

Typical black-and-white-scanned image.

- 300 pixels/inch.
- 8.5-by-11 inches.
- 300 × 8.5 × 300 × 11 = 8.415 million bits.

Observation. Bits are mostly white.

Typical amount of text on a page.

40 lines × 75 chars per line = 3,000 chars.

A typical bitmap, with run lengths for each row

18

Variable-length codes

Use different number of bits to encode different chars.

Ex. Morse code: ••• - - - ••• Letters Numbers Issue. Ambiguity. C D SOS ? E F IAMIE ? G EEWNI ? H I V7 ? Κ I. N In practice. Use a medium gap to 0 separate codewords. codeword for S is a prefix of codeword for V . . .

> Y 7

___.

▶ basics

run-length coding

Huffman compression

LZW compression

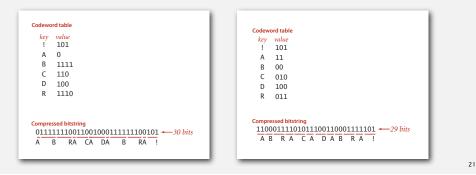

Variable-length codes

- Q. How do we avoid ambiguity?
- A. Ensure that no codeword is a prefix of another.
- Ex 1. Fixed-length code.
- Ex 2. Append special stop char to each codeword.
- Ex 3. General prefix-free code.

Prefix-free codes: trie representation

- Q. How to represent the prefix-free code?
- A. A binary trie!
- Chars in leaves.
- Codeword is path from root to leaf.

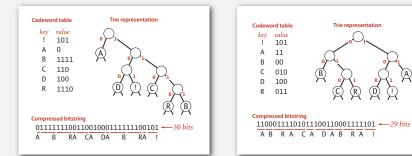

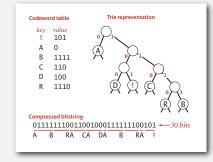

Compression.

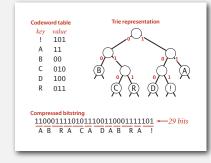

- Method 1: start at leaf; follow path up to the root; print bits in reverse.
- Method 2: create ST of key-value pairs.

Expansion.

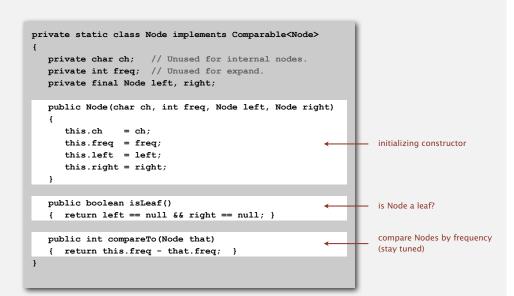

- Start at root.
- Go left if bit is 0; go right if 1.
- If leaf node, print char and return to root.

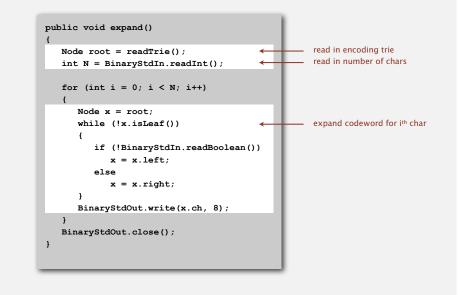

Huffman trie node data type

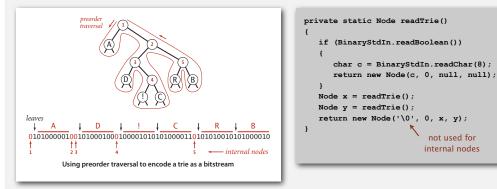

23

Running time. Linear in input size N.

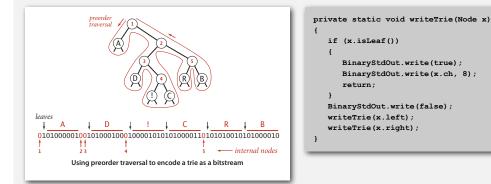

Prefix-free codes: how to transmit

- Q. How to read in the trie?
- A. Reconstruct from preorder traversal of trie.

Prefix-free codes: how to transmit

- Q. How to write the trie?
- A. Write preorder traversal of trie; mark leaf and internal nodes with a bit.

Note. If message is long, overhead of transmitting trie is small.

25

Shannon-Fano codes

Q. How to find best prefix-free code?

Shannon-Fano algorithm:

- Partition symbols S into two subsets S_0 and S_1 of (roughly) equal frequency.
- Codewords for symbols in S₀ start with 0; for symbols in S₁ start with 1.
- Recur in S₀ and S₁.

char	freq	encoding
A	5	0
с	1	0
S ₀ = co	dewords	starting with 0

char	freq	encoding
в	2	1
D	1	1
R	2	1
!	1	1

 $S_1 = codewords \ starting \ with \ 1$

Problem 1. How to divide up symbols? Problem 2. Not optimal!

Q. How to find best prefix-free code?

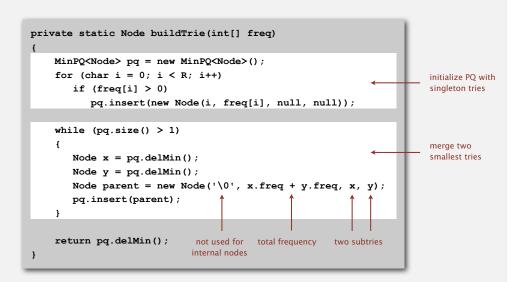

Huffman algorithm:

- Count frequency freq[i] for each char i in input.
- Start with one node corresponding to each char i (with weight freg[i]).
- Repeat until single trie formed:
- select two tries with min weight freq[i] and freq[j]
- merge into single trie with weight freq[i] + freq[j]

Applications:

Constructing a Huffman encoding trie: Java implementation

Constructing a Huffman encoding trie demo

Huffman encoding summary

Proposition. [Huffman 1950s] Huffman algorithm produces an optimal prefix-free code.

Implementation.

- Pass 1: tabulate char frequencies and build trie.
- Pass 2: encode file by traversing trie or lookup table.

Running time. Using a binary heap \Rightarrow $N + R \log R$.

29

:	:		AD	86		

Statistical methods

Static model. Same model for all texts.

- Fast.
- Not optimal: different texts have different statistical properties.
- Ex: ASCII, Morse code.

Dynamic model. Generate model based on text.

- Preliminary pass needed to generate model.
- Must transmit the model.
- Ex: Huffman code.

Adaptive model. Progressively learn and update model as you read text.

- More accurate modeling produces better compression.
- Decoding must start from beginning.
- Ex: LZW.

Lempel-Ziv-Welch compression

LZW compression.

- Create ST associating *W*-bit codewords with string keys.
- Initialize ST with codewords for single-char keys.
- Find longest string s in ST that is a prefix of unscanned part of input.
- Write the *W*-bit codeword associated with *s*.
- longest prefix match

 $(C)^{43}$ (D)

(A)85

(A) 87

(**B**)42

 $(R)_{82}$

(C) 84 (D) 86

(A)8

- Add s + c to ST, where c is next char in the input.
- Q. How to represent LZW compression code table?
- A. A trie to support longest prefix match.
