### Fibonacci heaps

Theorem. [Fredman-Tarjan 1986] Starting from an empty Fibonacci heap, any sequence of *m* INSERT, EXTRACT-MIN, and DECREASE-KEY operations involving *n* INSERT operations takes  $O(m + n \log n)$  time.

Fibonacci Heaps and Their Uses in Improved Network **Optimization Algorithms** 

MICHAEL L. FREDMAN University of California, San Diego, La Jolla, California AND

ROBERT ENDRE TARIAN AT&T Bell Laboratories, Murray Hill, New Jersey

Abstract. In this paper we develop a new data structure for implementing heaps (priority queues). Our structure, *Flowaeci heaps* (abserviated *F-heaps*), extends the binomial queues proposed by 'viiilemin and atudie further by Bowe. F-heaps any support a thirtyer (below from an *e*-heaps in (Alego) amorized time and all other standard heap opentions in O(1) amorized time. Using F-heaps we are able to obtain imported running time for several network or figurization algorithms. In particular, we othain the following uncercase bounds, where *a* is the number of vertices and *m* the number of odges in the problem gapti:

- O(n) og n + m) for the single-source shortest path problem with nonnegative edge lengths, improved from O(m)og<sub>0m+n</sub>,p);
   O(n<sup>2</sup>log n + m0) for the all-pairs shortest path problem, improved from O(m)og<sub>0m+n</sub>,p);
   O(n<sup>2</sup>log n + m0) for the assignment problem (weighted bipartite matching), improved from
- $O(nm\log_{n(n+2)}n);$ (4)  $O(m\beta(n, n))$  for the minimum spanning tree problem, improved from  $O(m\log\log_{n(n+2)}n)$ , where  $\beta(n, n) = \min |1|\log^n n \le m/n|$ . Note that  $\beta(m, n) \le \log^n n$  if  $m \ge n$ .

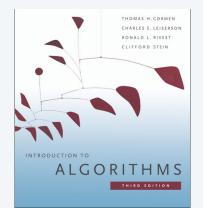

Of these results, the improved bound for minimum spanning trees is the most striking, although all the results give asymptotic improvements for graphs of appropriate densities.

### Fibonacci heaps

Theorem. [Fredman-Tarjan 1986] Starting from an empty Fibonacci heap, any sequence of *m* INSERT, EXTRACT-MIN, and DECREASE-KEY operations involving *n* INSERT operations takes  $O(m + n \log n)$  time.

#### History.

- Ingenious data structure and application of amortized analysis.
- · Original motivation: improve Dijkstra's shortest path algorithm from  $O(m \log n)$  to  $O(m + n \log n)$ .
- · Also improved best-known bounds for all-pairs shortest paths, assignment problem, minimum spanning trees.

#### SECTION 19.1

### structure

- ▶ insert
- ▶ extract the minimum
- ▶ decrease key
- bounding the rank
- ▶ meld and delete

## Fibonacci heaps

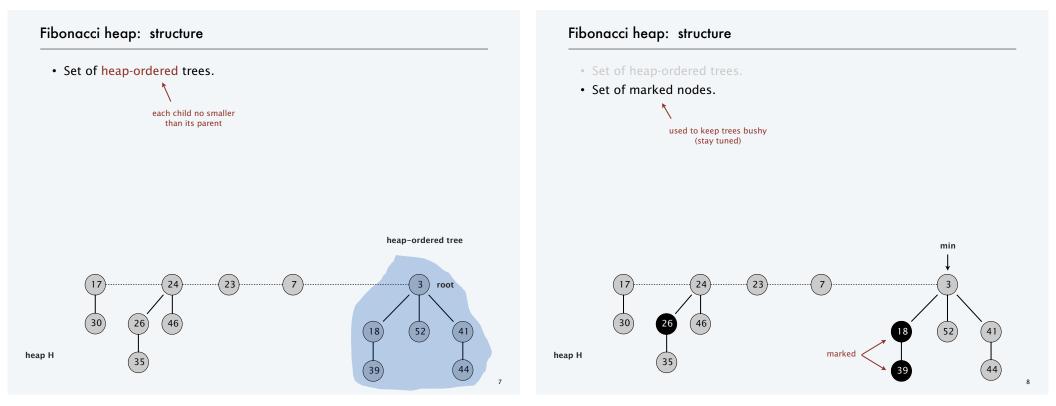

### Basic idea.

- Similar to binomial heaps, but less rigid structure.
- Binomial heap: eagerly consolidate trees after each INSERT; implement DECREASE-KEY by repeatedly exchanging node with its parent.

• Fibonacci heap: lazily defer consolidation until next EXTRACT-MIN; implement DECREASE-KEY by cutting off node and splicing into root list.

**Remark.** Height of Fibonacci heap is  $\Theta(n)$  in worst case, but it doesn't use sink or swim operations.

### Fibonacci heap: structure

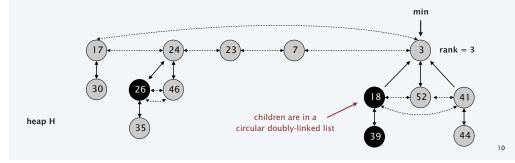

#### Heap representation.

- Store a pointer to the minimum node.
- Maintain tree roots in a circular, doubly-linked list.

### Fibonacci heap: representation

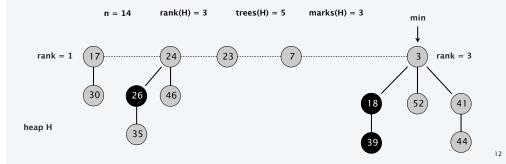

#### Node representation. Each node stores:

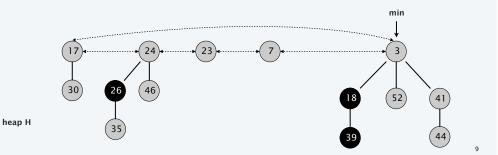

- A pointer to its parent.
- A pointer to any of its children.
- A pointer to its left and right siblings.
- Its rank = number of children.
- Whether it is marked.

### Fibonacci heap: notation

notation	meaning
п	number of nodes
rank(x)	number of children of node <i>x</i>
rank(H)	max rank of any node in heap $H$
trees(H)	number of trees in heap H
marks(H)	number of marked nodes in heap H

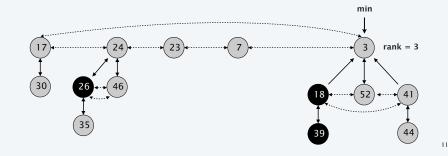

### Fibonacci heap: representation

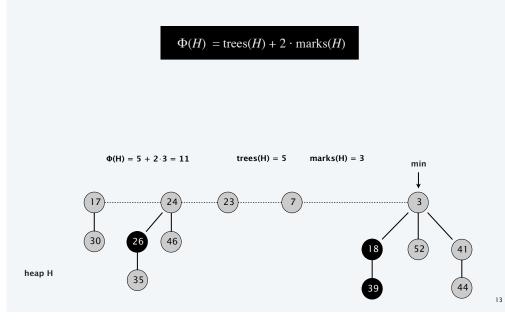

#### Operations we can do in constant time:

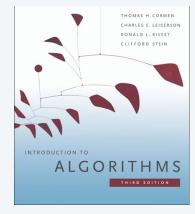

- Find the minimum element.
- Merge two root lists together.
- Determine rank of a root node.
- Add or remove a node from the root list.
- Remove a subtree and merge into root list.
- Link the root of a one tree to root of another tree.

## Fibonacci heap: potential function

### Potential function.

### Linking operation

Useful primitive. Combine two trees  $T_1$  and  $T_2$  of rank k.

- Make larger root be a child of smaller root.
- Resulting tree T' has rank k + 1.

- Delete min; meld its children into root list; update min.
- Consolidate trees so that no two roots have same rank.

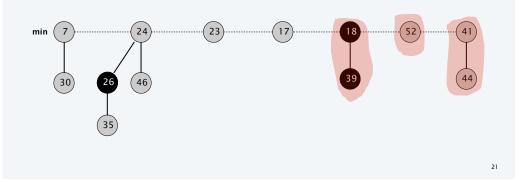

- Delete min; meld its children into root list; update min.
- Consolidate trees so that no two roots have same rank.

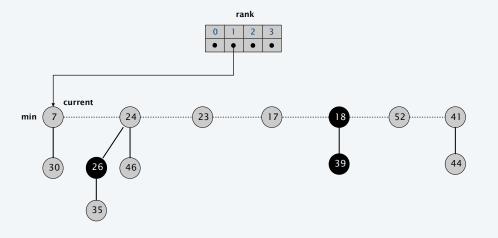

## Fibonacci heap: extract the minimum

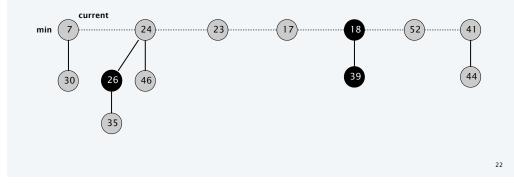

- Delete min; meld its children into root list; update min.
- · Consolidate trees so that no two roots have same rank.

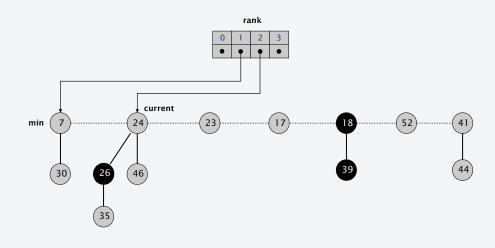

### Fibonacci heap: extract the minimum

- · Consolidate trees so that no two roots have same rank.

# rank current min 52 17 30 24 23 33

## Fibonacci heap: extract the minimum

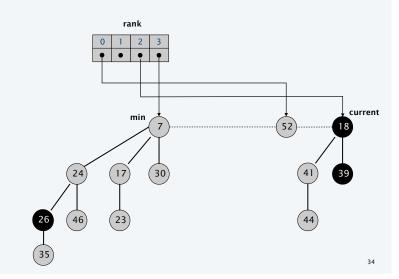

- Delete min; meld its children into root list; update min.
- · Consolidate trees so that no two roots have same rank.

#### stop (no two trees have same rank)

### Fibonacci heap: extract the minimum

- Delete min; meld its children into root list; update min.
- · Consolidate trees so that no two roots have same rank.

### Fibonacci heap: extract the minimum analysis

#### Actual cost. $c_i = O(rank(H)) + O(trees(H))$ .

- O(rank(H)) to meld min's children into root list.  $\leftarrow \leq rank(H)$  children
- O(rank(H)) + O(trees(H)) to update min.
- *O*(*rank*(*H*)) + *O*(*trees*(*H*)) to consolidate trees. ← number of roots decreases by 1 after
- $\leftarrow$   $\leq$  rank(H) + trees(H) 1 root nodes
  - each linking operation

#### Change in potential. $\Delta \Phi \leq rank(H') + 1 - trees(H)$ .

- No new nodes become marked.
- $trees(H') \leq rank(H') + 1$ .  $\leftarrow$  no two trees have same rank after consolidation

#### Amortized cost. $O(\log n)$ .

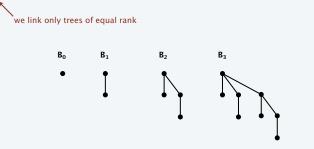

- $\hat{c}_i = c_i + \Delta \Phi = O(rank(H)) + O(rank(H')).$
- The rank of a Fibonacci heap with *n* elements is  $O(\log n)$ .

Fibonacci lemma (stay tuned)

 $\Phi(H) = \text{trees}(H) + 2 \cdot \text{marks}(H)$ 

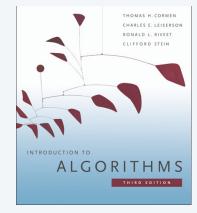

## Fibonacci heap vs. binomial heaps

Observation. If only INSERT and EXTRACT-MIN operations, then all trees are binomial trees.

Binomial heap property. This implies  $rank(H) \leq \log_2 n$ .

**Fibonacci heap property.** Our DECREASE-KEY implementation will not preserve this property, but we will implement it in such a way that  $rank(H) \le \log_{\phi} n$ .

## Fibonacci heap: decrease key analysis

Actual cost.  $c_i = O(c)$ , where *c* is the number of cuts.

- *O*(1) time for changing the key.
- O(1) time for each of c cuts, plus melding into root list.

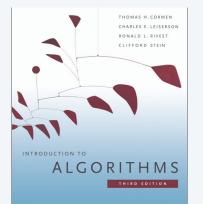

Change in potential.  $\Delta \Phi = O(1) - c$ .

- trees(H') = trees(H) + c.
- $marks(H') \leq marks(H) c + 2$ . each cut (except first) unmarks a node
- $\Delta \Phi \leq c + 2 \cdot (-c + 2) = 4 c$ .

last cut may or may not mark a node

Amortized cost.  $\hat{c}_i = c_i + \Delta \Phi = O(1)$ .

 $\Phi(H) = \text{trees}(H) + 2 \cdot \text{marks}(H)$

Insert. *O*(1). Delete-min. O(rank(H)) amortized. Decrease-key. *O*(1) amortized.

Fibonacci lemma. Let *H* be a Fibonacci heap with *n* elements. Then,  $rank(H) = O(\log n)$ .

number of nodes is exponential in rank

### Bounding the rank

Lemma 1. Fix a point in time. Let x be a node of rank k, and let  $y_1, ..., y_k$  denote its current children in the order in which they were linked to x. Then:

### Pf.

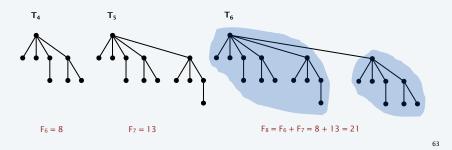

- When  $y_i$  was linked into x, x had at least i 1 children  $y_1, \ldots, y_{i-1}$ .
- Since only trees of equal rank are linked, at that time  $rank(y_i) = rank(x) \ge i 1$ .
- Since then,  $y_i$  has lost at most one child (or  $y_i$  would have been cut).
- Thus, right now  $rank(y_i) \ge i 2$ .

### Bounding the rank

Lemma 1. Fix a point in time. Let x be a node of rank k, and let  $y_1, ..., y_k$  denote its current children in the order in which they were linked to x. Then:

$$rank(y_i) \geq \begin{cases} 0 & \text{if } i = 1\\ i - 2 & \text{if } i \geq 2 \end{cases}$$

### **Def.** Let $T_k$ be smallest possible tree of rank k satisfying property.

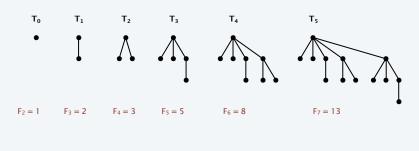

## Bounding the rank

Lemma 1. Fix a point in time. Let x be a node of rank k, and let  $y_1, ..., y_k$  denote its current children in the order in which they were linked to x. Then:

$$rank(y_i) \geq \begin{cases} 0 & \text{if } i = 1\\ i - 2 & \text{if } i \geq 2 \end{cases}$$

### Bounding the rank

61

Lemma 2. Let  $s_k$  be minimum number of elements in any Fibonacci heap of rank k. Then  $s_k \ge F_{k+2}$ , where  $F_k$  is the  $k^{th}$  Fibonacci number.

- Pf. [by strong induction on k]
  - Base cases:  $s_0 = 1$  and  $s_1 = 2$ .
  - Inductive hypothesis: assume  $s_i \ge F_{i+2}$  for i = 0, ..., k-1.
  - As in Lemma 1, let let  $y_1, ..., y_k$  denote its current children in the order in which they were linked to *x*.

$$s_k \ge 1 + 1 + (s_0 + s_1 + ... + s_{k-2})$$
 (Lemma 1)  
 $\ge (1 + F_1) + F_2 + F_3 + ... + F_k$  (inductive hypothesis)  
 $= F_{k+2}$ . • (Fibonacci fact 1)

64

 $y_k$ 

### Bounding the rank

Fibonacci lemma. Let *H* be a Fibonacci heap with *n* elements. Then,  $rank(H) \le \log_{\oplus} n$ , where  $\phi$  is the golden ratio =  $(1 + \sqrt{5})/2 \approx 1.618$ .

#### Pf.

- Let *H* is a Fibonacci heap with *n* elements and rank *k*.
- Then  $n \ge F_{k+2} \ge \phi^k$ .

Lemma 2 Fibonacci Fact 2

• Taking logs, we obtain  $rank(H) = k \le \log_{\phi} n$ .

## Fibonacci fact 1

**Def.** The Fibonacci sequence is: 0, 1, 1, 2, 3, 5, 8, 13, 21, ...

$$F_k = \begin{cases} 0 & \text{if } k = 0\\ 1 & \text{if } k = 1\\ F_{k-1} + F_{k-2} & \text{if } k \ge 2 \end{cases}$$

Fibonacci fact 1. For all integers  $k \ge 0$ ,  $F_{k+2} = 1 + F_0 + F_1 + \ldots + F_k$ .

**Pf.** [by induction on *k*]

- Base case:  $F_2 = 1 + F_0 = 2$ .
- Inductive hypothesis: assume  $F_{k+1} = 1 + F_0 + F_1 + \ldots + F_{k-1}$ .

$$F_{k+2} = F_k + F_{k+1}$$
 (definition)  
=  $F_k + (1 + F_0 + F_1 + \dots + F_{k-1})$  (inductive hypothesis)  
=  $1 + F_0 + F_1 + \dots + F_{k-1} + F_k$ . (algebra)

65

## Fibonacci fact 2

**Def.** The Fibonacci sequence is: 0, 1, 1, 2, 3, 5, 8, 13, 21, ...

$$F_k = \begin{cases} 0 & \text{if } k = 0 \\ 1 & \text{if } k = 1 \\ F_{k-1} + F_{k-2} & \text{if } k \ge 2 \end{cases}$$

Fibonacci fact 2.  $F_{k+2} \ge \phi^k$ , where  $\phi = (1 + \sqrt{5}) / 2 \approx 1.618$ . Pf. [by induction on k]

- Base cases:  $F_2 = 1 \ge 1$ ,  $F_3 = 2 \ge \phi$ .
- Inductive hypotheses: assume  $F_k \ge \phi^k$  and  $F_{k+1} \ge \phi^{k+1}$

$$F_{k+2} = F_k + F_{k+1} \quad (\text{definition})$$

$$\geq \varphi^{k-1} + \varphi^{k-2} \quad (\text{inductive hypothesis})$$

$$= \varphi^{k-2}(1 + \varphi) \quad (\text{algebra})$$

$$= \varphi^{k-2} \varphi^2 \quad (\varphi^2 = \varphi + 1)$$

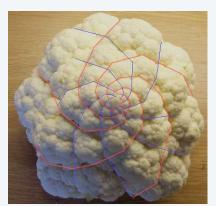

$$= \varphi^k \quad \bullet \qquad (\text{algebra})$$

### **Brodal queues**

Q. Can we achieve same running time as for Fibonacci heap but with worst-case bounds per operation (instead of amortized)?

Theory. [Brodal 1996] Yes.

Worst-Case Efficient Priority Queues\*

Gerth Stølting Brodal<sup>†</sup>

#### Abstract

An implementation of priority queues is presented that supports the operations MAKEQUEUE, FINDMIN, INSERT, MELD and DECREASEKEY in worst case time O(1) and DELETEMIN and DELETE in worst case time  $O(\log n)$ . The space requirement is linear. The data structure presented is the first achieving this worst case performance.

Practice. Ever implemented? Constants are high (and requires RAM model).

77

Fibonacci heaps: practice

- Q. Are Fibonacci heaps useful in practice?
- A. They are part of LEDA and Boost C++ libraries. (but other heaps seem to perform better in practice)

### Strict Fibonacci heaps

Q. Can we achieve same running time as for Fibonacci heap but with worst-case bounds per operation (instead of amortized) in pointer model?

of Athens

Theory. [Brodal-Lagogiannis-Tarjan 2002] Yes.

ABSTRACT

We present the first pointer-based heap implementation with time bounds matching those of Fibonacci heaps in the worst case. We support make-heap, insert, find-min, meld and decrease-key in worst-case O(1) time, and delete and deletemin in worst-case  $O(\lg n)$  time, where n is the size of the heap. The data structure uses linear space.

A previous, very complicated, solution achieving the same time bounds in the RAM model made essential use of arrays and extensive use of redundant counter schemes to maintain balance. Our solution uses neither. Our key simplification is to discard the structure of the smaller heap when doing a meld. We use the pigeonhole principle in place of the redundant counter mechanism.

### Pairing heaps

Pairing heap. A self-adjusting heap-ordered general tree.

Abstract. Recently, Fredman and Tarjan invented a new, especially efficient form of heap (priority queue) called the Fibonacci heap. Although theoretically efficient, Fibonacci heaps are complicated to implement and not as fast in practice as other kinds of heaps. In this paper we describe a new form of heap, called the pairing heap, intended to be competitive with the Fibonacci heap in theory and easy to implement and fast in practice. We provide a partial complexity analysis of pairing heaps. Complete analysis remains an open problem.

Theory. Same amortized running times as Fibonacci heaps for all operations except DECREASE-KEY.

- O(log n) amortized. [Fredman et al. 1986]
- $\Omega(\log \log n)$  lower bound on amortized cost. [Fredman 1999]
- $2\sqrt{O(\log \log n)}$  amortized. [Pettie 2005]

## Pairing heaps

Pairing heap. A self-adjusting heap-ordered general tree.

Practice. As fast as (or faster than) the binary heap on some problems. Included in GNU C++ library and LEDA.

Abstract		

### Priority queues with integer priorities

Assumption. Keys are integers between 0 and C.

Theorem. [Thorup 2004] There exists a priority queue that supports INSERT, FIND-MIN, and DECREASE-KEY in constant time and EXTRACT-MIN and DELETE-KEY in either  $O(\log \log n)$  or  $O(\log \log C)$  time.

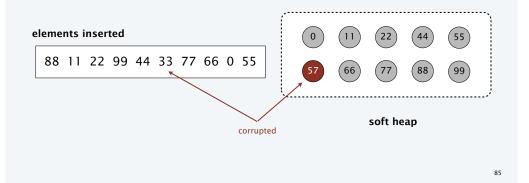

Corollary 1. Can implement Dijkstra's algorithm in either  $O(m \log \log n)$  or  $O(m \log \log C)$  time.

Corollary 2. Can sort *n* integers in  $O(n \log \log n)$  time.

Computational model. Word RAM.

### Soft heaps

Goal. Break information-theoretic lower bound by allowing priority queue to corrupt 10% of the keys (by increasing them).

## Soft heaps

Goal. Break information-theoretic lower bound by allowing priority queue to corrupt 10% of the keys (by increasing them).

Theorem. [Chazelle 2000] Starting from an empty soft heap, any sequence of n INSERT, MIN, EXTRACT-MIN, MELD, and DELETE operations takes O(n) time and at most 10% of its elements are corrupted at any given time.

The Soft Heap: An Approximate Priority Queue with Optimal Error Rate

BERNARD CHAZELLE

Princeton University, Princeton, New Jersey, and NEC Research Institute

Abstract. A simple variant of a priority queue, called a soft heap, is introduced. The data structure supports the usual operations: insert, delete, med), and findmin. Its novely is to beat the logarithmic bound on the complexity of a heap in a comparison-based model. To break this information-theoretic barrier, the entropy of the data structure is reduced by artificially raising the values of certain keys. Given any mixed sequence of *n* operations, a soft heap with error rate e( for any  $0 < \epsilon = 1/2$ ) ensures that, at any time, at most *en* of its items have their keys raised. The amortized complexity of each operation is constant, except for insert, which takes  $O(\log 1/2)$  time. The soft heap is optimal for any value of *e* in a comparison-based model. The data structure is prively pointer-based. No arrays are used and no numeric assumptions are made on the keys. The main idea behind the soft heap is to move items across the data structure. The soft heap cale cale core operarve the heap cale cale of the data future. The soft heap cale cale cale or approximate medians and percentiles optimally. It is also useful for approximate sorting and for computing minimum spanning trees of general graphs.

### Soft heaps

Goal. Break information-theoretic lower bound by allowing priority queue to corrupt 10% of the keys (by increasing them).

#### Representation.

- Set of binomial trees (with some subtrees missing).
- Each node may store several elements.
- Each node stores a value that is an upper bound on the original keys.
- Binomial trees are heap-ordered with respect to these values.

### Soft heaps

Goal. Break information-theoretic lower bound by allowing priority queue to corrupt 10% of the keys (by increasing them).

- Q. Brilliant. But how could it possibly be useful?
- Ex. Linear-time deterministic selection. To find *k*<sup>th</sup> smallest element:
  - Insert the *n* elements into soft heap.
  - Extract the minimum element *n* / 2 times.
- The largest element deleted  $\geq 4n / 10$  elements and  $\leq 6n / 10$  elements.

- Can remove  $\ge 5n / 10$  of elements and recur.
- $T(n) \leq T(3n/5) + O(n) \Rightarrow T(n) = O(n)$ .

# Soft heaps

Theorem. [Chazelle 2000] There exists an  $O(m \alpha(m, n))$  time deterministic algorithm to compute an MST in a graph with *n* nodes and *m* edges.

Algorithm. Borůvka + nongreedy + divide-and-conquer + soft heap + ...

#### A Minimum Spanning Tree Algorithm with Inverse-Ackermann Type Complexity

BERNARD CHAZELLE

Princeton University, Princeton, New Jersey, and NEC Research Institute

Abstract. A deterministic algorithm for computing a minimum spanning tree of a connected graph is presented. Its running time is  $O(m\alpha(m, n))$ , where  $\alpha$  is the classical functional inverse of Ackermann's function and n (respectively, m) is the number of vertices (respectively, edges). The algorithm is comparison-based: it uses pointers, not arrays, and it makes no numeric assumptions on the edge costs.
