# Topic 5:      Activation Records

COS 320

Compiling Techniques

Princeton University  
Spring 2018

Prof. David August

1

---

## Activation Records

---

- Modern imperative programming languages typically have *local* variables.
  - Created upon entry to function.
  - Destroyed when function returns.
- Each invocation of a function has its own *instantiation* of local variables.
  - Recursive calls to a function require several instantiations to exist simultaneously.
  - Functions return only after all functions it calls have returned  $\Rightarrow$  last-in-first-out (LIFO) behavior.
  - A LIFO structure called a *stack* is used to hold each instantiation.
- The portion of the stack used for an invocation of a function is called the function's *stack frame* or *activation record*.

2

---

## The Stack

---

### The Stack

- Used to hold local variables.
- Large array which typically grows downwards in memory toward lower addresses, shrinks upwards.
- Push(r1):

```
stack_pointer--;  
M[stack_pointer] = r1;
```
- r1 = Pop():

```
r1 = M[stack_pointer];  
stack_pointer++;
```
- Previous activation records need to be accessed, so push/pop not sufficient.
  - Treat stack as array with index off of `stack_pointer`.
  - Push and pop entire activation records.

3

## Example

Consider:

```
let
  function g(x:int) =
    let
      var y := 10
    in
      x + y
    end
  function h(y:int):int =
    y + g(y)
in
  h(4)
end
```

4

## Example

**Step 1:  $h(4)$  called**

Chunk of memory allocated on the stack in order to hold local variables of  $h$ . The activation record (or stack frame) of  $h$  is pushed onto the stack.

Stack	
Frame for h	y=4

**Step 2:  $g(4)$  called**

Activation record for  $g$  allocated (pushed) on stack.

Stack	
Frame for h	y=4
Stack	
Frame for g	x=4 y=10

5

## Example

**Step 3:  $g(4)$  returns with value 14**

Activation record for  $g$  deallocated (popped) from stack.

Stack	
Frame for h	y=4 rv = 14

**Step 4:  $h(4)$  returns with value 18**

Activation record for  $h$  deallocated (popped) from stack. Stack now empty.

6

## Recursive Example

Can have multiple stack frames for same function (different invocations) on stack at any given time due to recursion.

Consider:

```
let
  function fact(n:int):int =
    if n = 0 then 1
    else n * fact(n - 1)
in
  fact(3)
end
```

Step 1: Record for fact(3) pushed on stack.

Stack	
Frame	n=3
for fact	

7

## Recursive Example

Step 2: Record for fact(2) pushed on stack.

Stack	
Frame	n=3
for fact	
Stack	
Frame	n=2
for fact	

Step 3: Record for fact(1) pushed on stack.

Stack	
Frame	n=3
for fact	
Stack	
Frame	n=2
for fact	
Stack	
Frame	n=1
for fact	

8

## Recursive Example

Step 4: Record for fact(0) pushed on stack.

Stack	
Frame	n=3
for fact	
Stack	
Frame	n=2
for fact	
Stack	
Frame	n=1
for fact	
Stack	
Frame	n=0
for fact	

- Step 5: Record for fact(0) popped off stack, 1 returned.
- Step 6: Record for fact(1) popped off stack, 1 returned.
- Step 7: Record for fact(2) popped off stack, 2 returned.
- Step 8: Record for fact(3) popped off stack, 3 returned. Stack now empty.

9

## Functional Languages

---

In some functional languages (such as ML, Scheme), local variables cannot be stored on stack.

```
fun f(x) =  
  let  
    fun g(y) = x + y  
  in  
    g  
  end
```

**Consider:**

- val z = f(4)
- val w = z(5)

Assume variables are stack-allocated.

10

## Functional Languages

---

**Step 1: f(4) called.**

Frame for f(4) pushed, g returned, frame for f(4) popped.

Stack empty.

**Step 3: z(5) called**

Memory location containing x has been deallocated!

11

## Functional Languages

---

Combination of nested functions and functions returned as results (higher-order functions):

- Requires local variables to remain in existence even after enclosing function has been returned.
- Activation records must be allocated on heap, not stack.

**Concentrate on languages which use stack.**

12

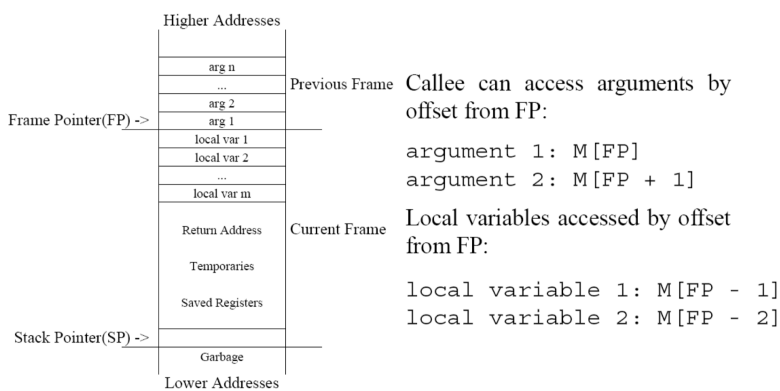

# Stack Frame Organizations

How is data organized in stack frame?

- Compiler can use any layout scheme that is convenient.
- Microprocessor manufactures specify “standard” layout schemes used by all compilers.
  - Sometimes referred to as *Calling Conventions*.
  - If all compilers use the same calling conventions, then functions compiled with one compiler can call functions compiled with another.
  - Essential for interaction with OS/libraries.

13

## Typical Stack Frame

14

## Stack Frame Example

Suppose `f(a1, a2)` calls `g(b1, b2, b3)`

**Step 1:**

**Step 2:**

15

## Stack Frame Example

Suppose  $f(a_1, a_2)$  calls  $g(b_1, b_2, b_3)$

**Step 3:**

Dynamic link (AKA Control link) points to the activation record of the caller.

- Optional if size of caller activation record is known at compile time.
- Used to restore stack pointer during return sequence.

16

## Stack Frame Example

Suppose  $f(a_1, a_2)$  calls  $g(b_1, b_2, b_3)$ , and returns.

**Step 4**

**Step 5**

17

## Parameter Passing

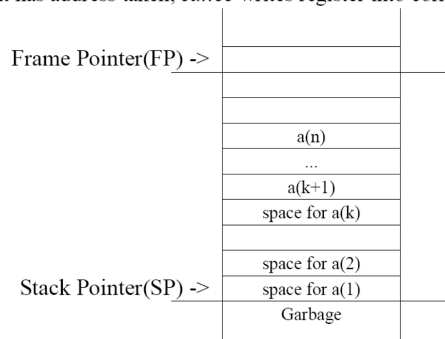

$f(a_1, a_2, \dots, a_n)$

- Registers are faster than memory.
- Compiler should keep values in register whenever possible.
- Modern calling convention: rather than placing  $a_1, a_2, \dots, a_n$  on stack frame, put  $a_1, \dots, a_k$  ( $k = 4$ ) in registers  $r_p, r_{p+1}, r_{p+2}, r_{p+3}$  and  $a_{k+1}, a_{k+2}, \dots, a_n$ .
- If  $r_p, r_{p+1}, r_{p+2}, r_{p+3}$  are needed for other purposes, callee function must save incoming argument(s) in stack frame.
- C language allows programmer to take address of formal parameter and guarantees that formals are located at consecutive memory addresses.
  - If address argument has address taken, then it must be written into stack frame.
  - Saving it in “saved registers” area of stack won’t make it consecutive with memory resident arguments.
  - Space must be allocated even if parameters are passed through register.

18

## Parameter Passing

If register argument has address taken, *callee* writes register into corresponding space.

19

## Registers

### Registers hold:

- Some Parameters
- Return Value
- Local Variables
- Intermediate results of expressions (temporaries)

### Stack Frame holds:

- Variables passed by reference or have their address taken (&)
- Variables that are accessed by procedures nested within current one.
- Variables that are too large to fit into register file.
- Array variables (address arithmetic needed to access array elements).
- Variables whose registers are needed for a specific purpose (parameter passing)
- *Spilled* registers. Too many local variables to fit into register file, so some must be stored in stack frame.

20

## Registers

Compilers typically place variables on stack until it can determine whether or not it can be promoted to a register (e.g. no references).

The assignment of variables to registers is done by the *Register Allocator*.

21

## Registers

---

Register state for a function must be saved before a callee function can use them.

Calling convention describes two types of registers.

- *Caller-save* registers are the responsibility of the calling function.
  - Caller-save register values are saved to the stack by the calling function if they will be used after the call.
  - The callee function can use caller-save registers without saving their original values.
- *Callee-save* registers are the responsibility of the called function.
  - Callee-save register values must be saved to the stack by called function before they can be used.
  - The caller (calling function) can assume that these registers will contain the same value before and after the call.

Placement of values into callee-save vs. caller-save registers is determined by the register allocator.

22

## Return Address and Return Value

---

A called function must be able to return to calling function when finished.

- Return address is address of instruction following the function call.
- Return address can be placed on stack or in a register.
- The *call* instruction in modern machines places the return address in a designated register.
- This return address is written to stack by callee function in non-leaf functions.

Return value is placed in designated register by callee function.

23

## Frame Resident Variables

---

- A variable *escapes* if:
  - it is passed by reference,
  - its address is taken, or
  - it is accessed from a nested function.
- Variables cannot be assigned a location at declaration time.
  - Escape conditions not known.
  - Assign provisional locations, decide later if variables can be promoted to registers.
- `escape` set to true by default.

24

## Static Links

In languages that allow nested functions (e.g. Tiger), functions must access outer function's stack frame.

```

let
  function f():int = let
    var a:=5
    function g(y:int):int = let
      var b:=10
      function h(z:int):int =
        if z > 10 then h(z / 2)
        else z + b * a
      in
        y + a + h(16)
      end
    in
      g(10)
    end
  in f() end

```

25

## Static Links

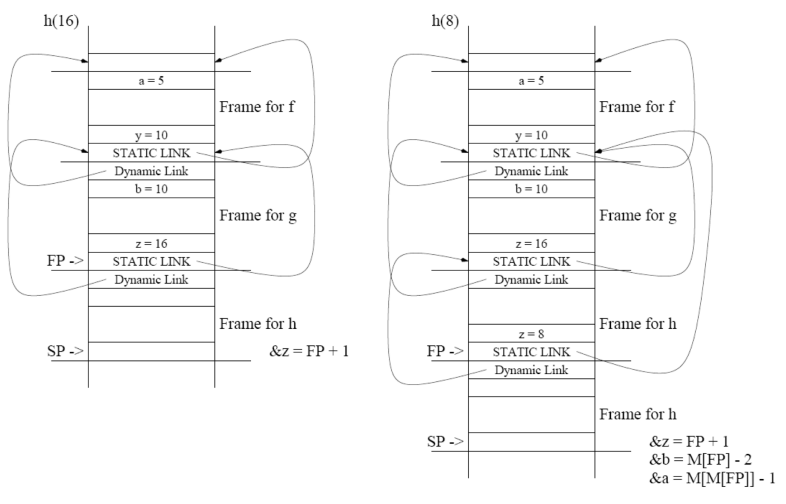

**Solution:**

Whenever f is called, it is passed pointer to most recent activation record of g that immediately encloses f in program text  $\Rightarrow$  Static Link (AKA Access Link).

26

## Static Links

27

- Need a chain of indirect memory references for each variable access.
- Number of indirect references = difference in nesting depth between variable declaration function and use function.
