Review: AM Modulation & Demodulation

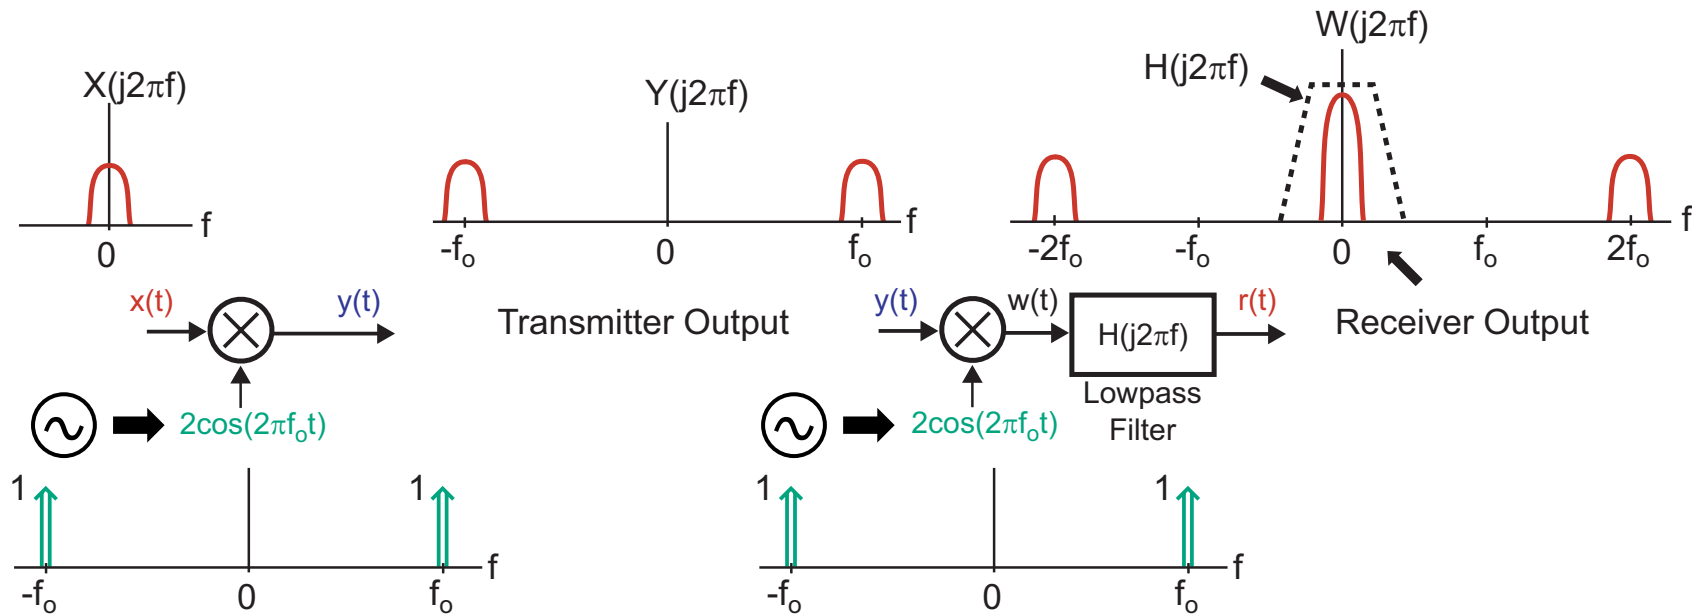

- **Multiplication** (*i.e. mixing*) operation **shifts in frequency**
- **Low-pass filtering** passes **only the desired baseband signal** at the receiver

Impact of a 90° phase shift

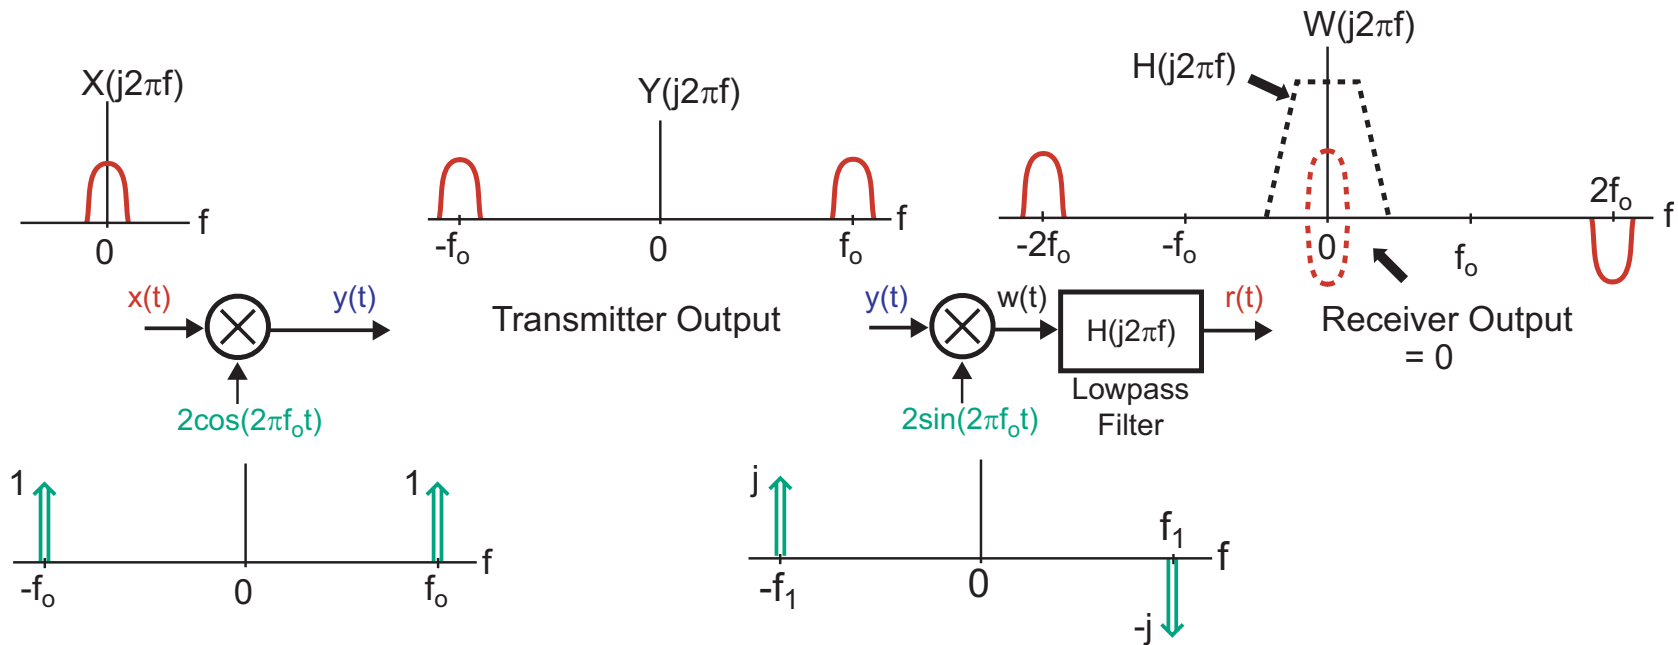

- Receiver uses **sine** instead of **cosine**: **no output**
 - $\sin(2\pi f_0 t)\cos(2\pi f_0 t) = \frac{1}{2} \sin(4\pi f_0 t)$
- Need to **synchronize phase** of transmitter and receiver **local oscillators** (**coherent** demodulation)

Coherent Demodulation: Frequency-domain analysis

- Transmitter and receiver oscillators **phase-synchronized**
- Demodulated copies **add constructively** at baseband

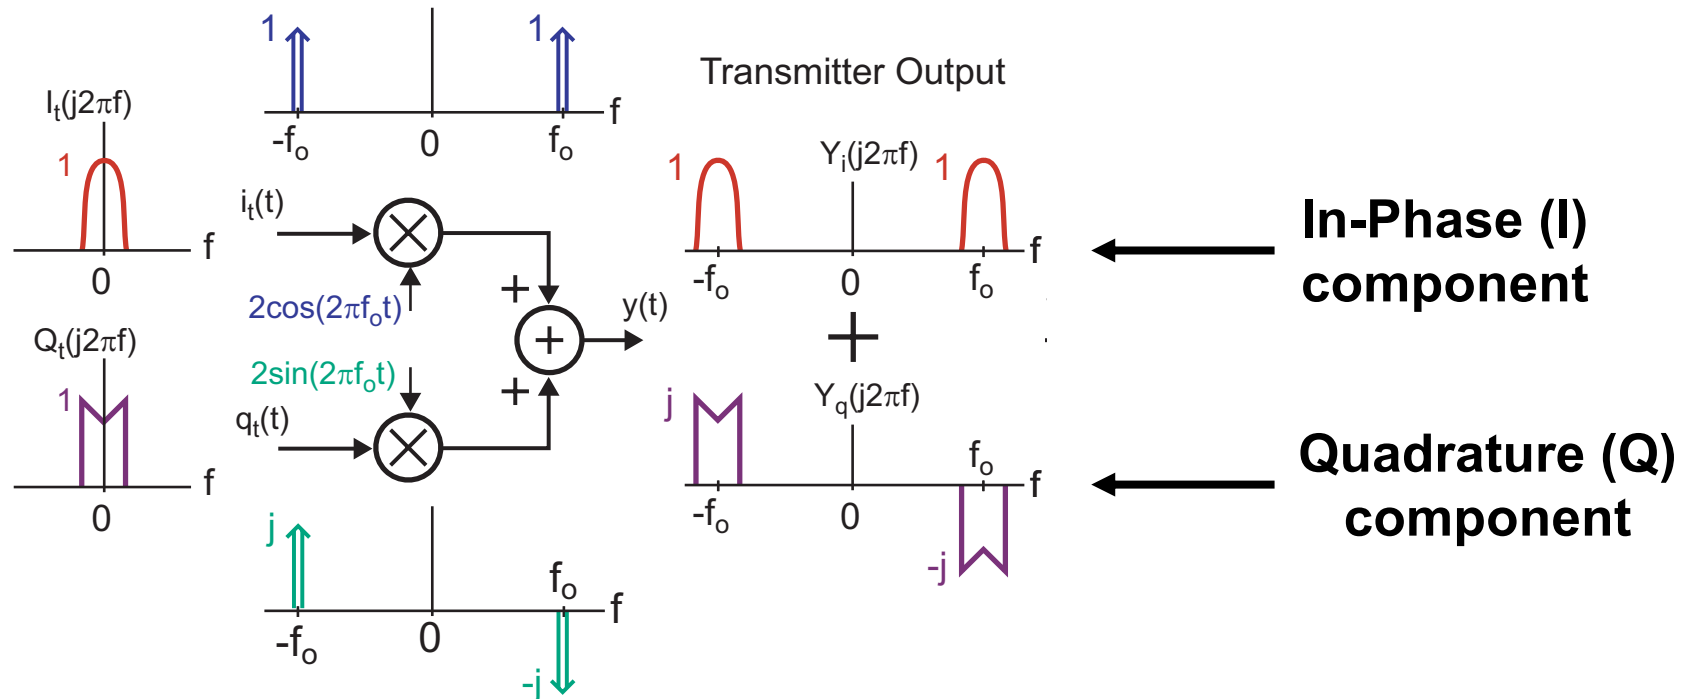

90° Phase Shift: Frequency-domain analysis

- Transmitter, receiver oscillators **are offset in phase by 90°**
- Demodulated copies **add destructively** at baseband
 - **Zero output from receiver**
- **Two separate channels!**

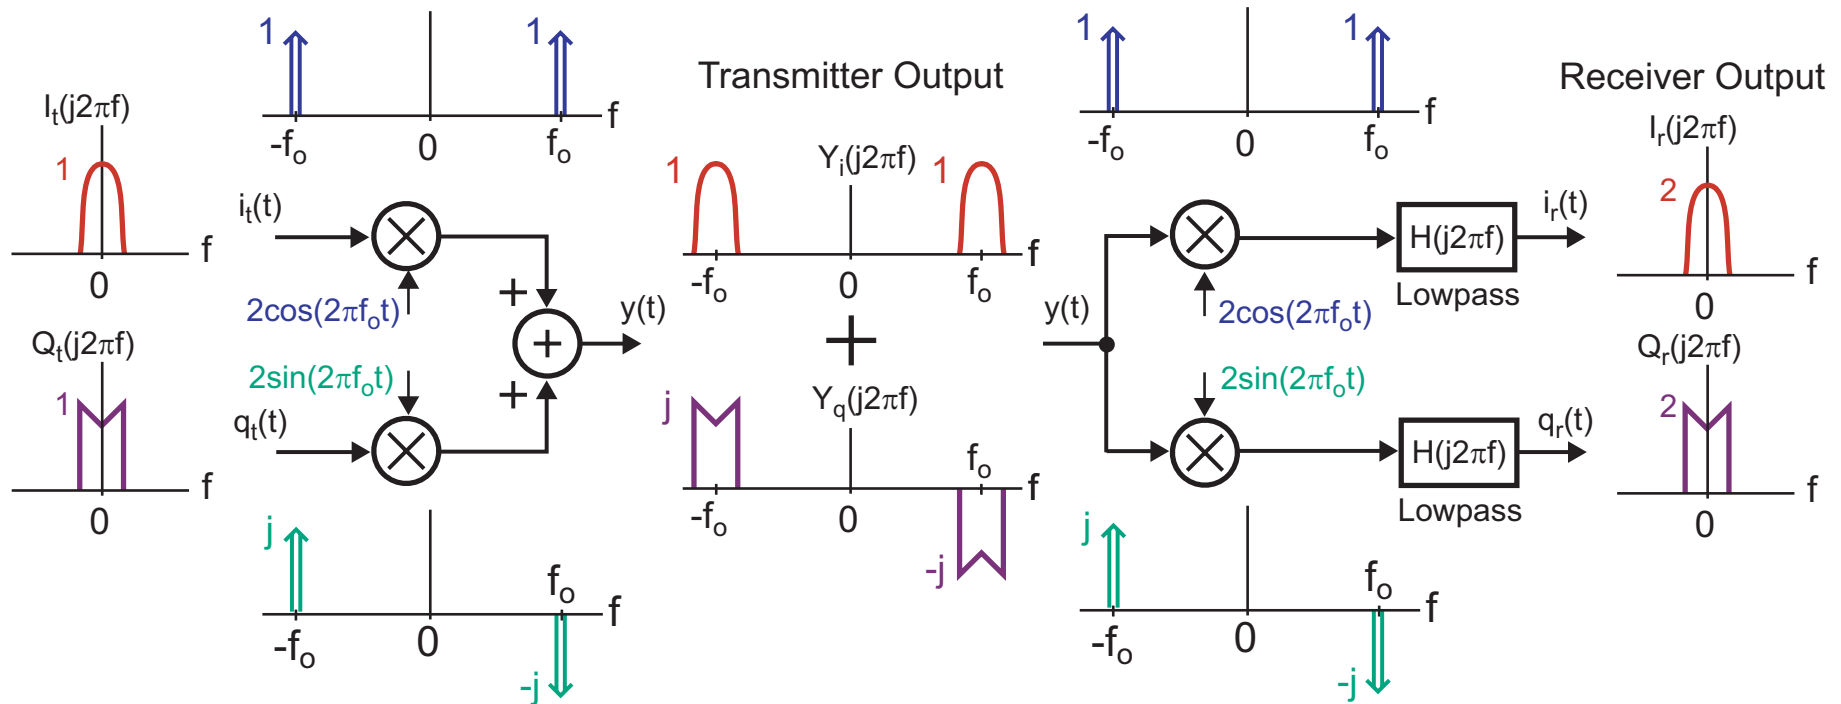

In-Phase/Quadrature Modulation

- Modulate each with a cosine & sine, sum the result

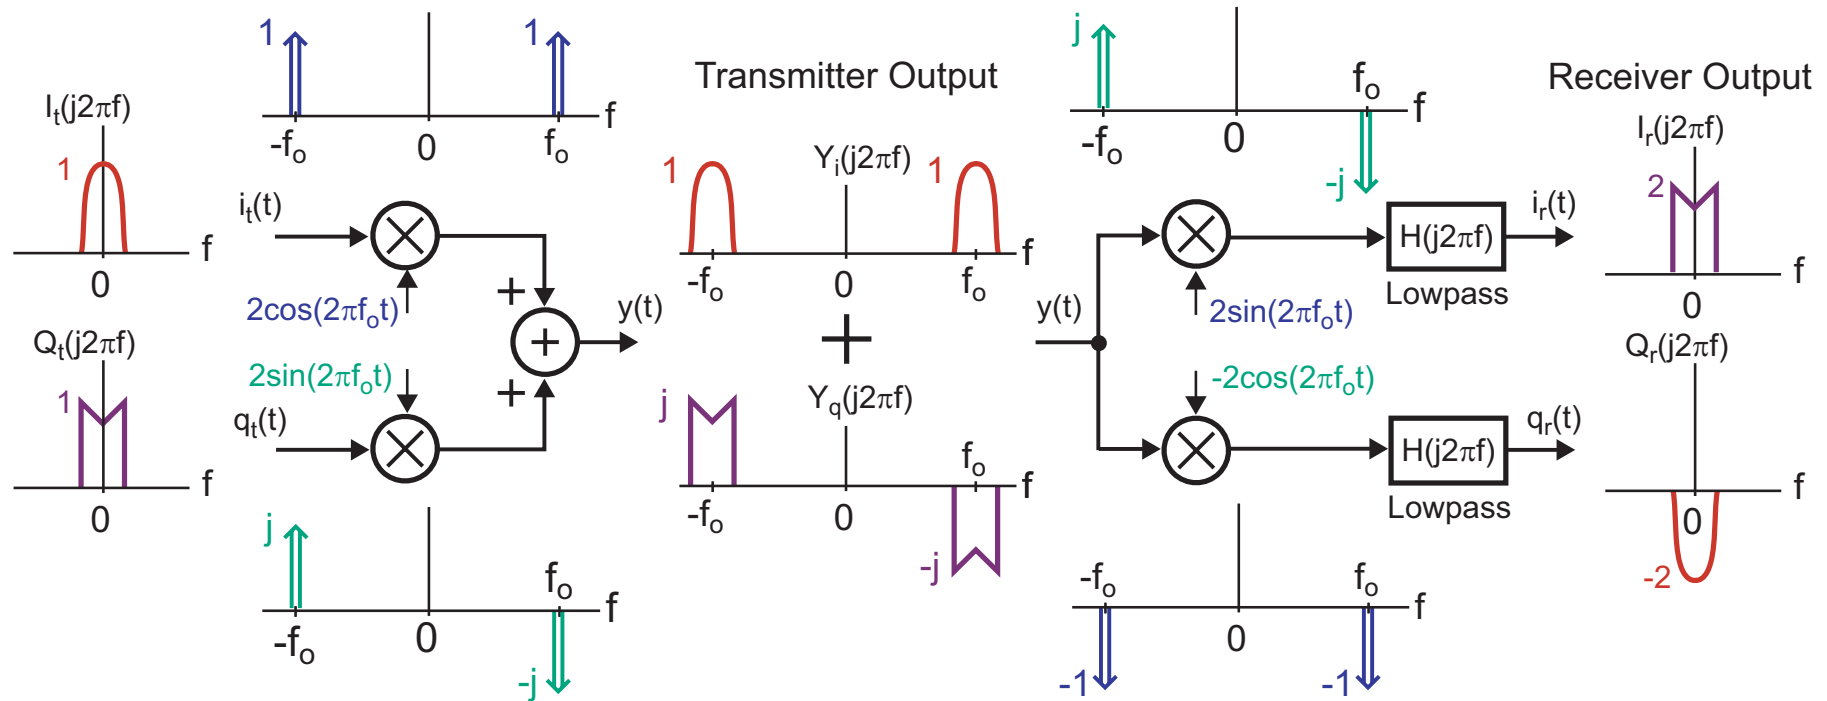

- I, Q signals occupy the same frequency band
 - One is real (for cos), one is imaginary (for sin)

In-Phase/Quadrature Demodulation

- Demodulate with **both a sine and a cosine**
 - Both I and Q channels are recovered!**

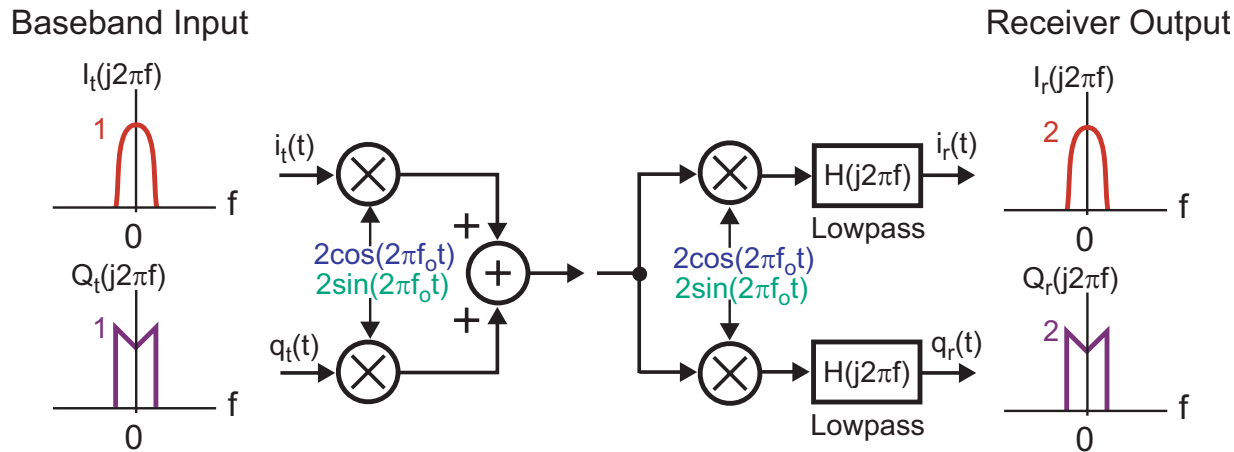

I/Q Demodulation: 90° Phase Shift

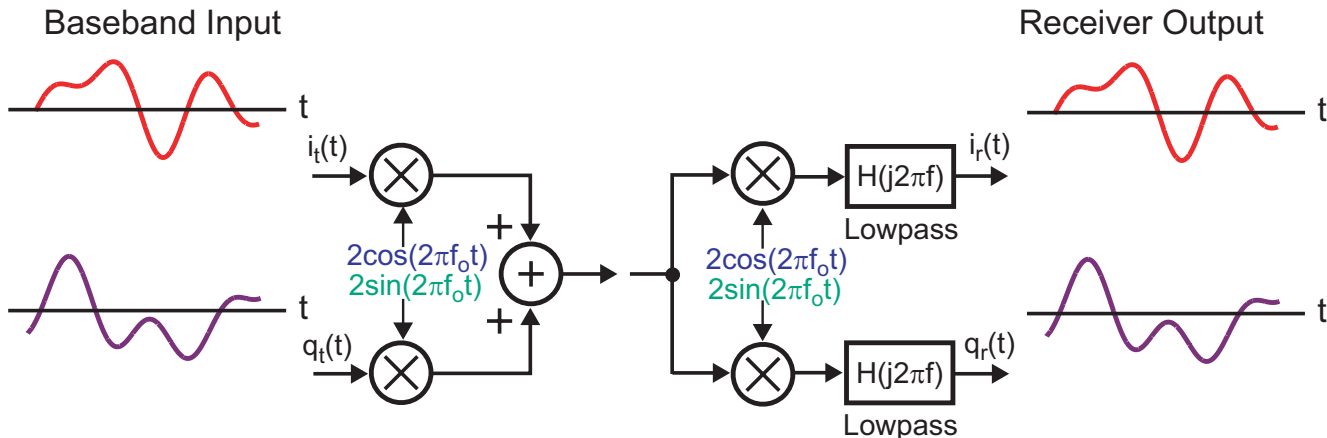

- I and Q channels get **swapped** at receiver
 - **Key observation:** No information is lost!

Summary of Analog I/Q modulation

- Frequency domain view

- Time domain view

I/Q modulation: Wrap-up

- I/Q modulation allows **twice the amount of information** to be sent **compared to basic AM**
- Impact of **phase offset** is to **swap I/Q**
- Impact of **frequency offset** is I/Q swapping (**small offset**)
 - Or **catastrophic corruption** (large offset) of received signal

Representing information with voltage

- **Encoding of pixel** at location (x, y) in a Black & White picture:
 - 0 Volts = Black
 - 1 Volt = White
 - 0.37 V = 37% Gray
 - etc...
- **Encoding of a picture:**
 - Scan points in prescribed order
 - Generate a continuous voltage waveform (**baseband signal**)

Let's build a P2P television network

One hop:

Many hops:

Why did our network fail?

1. Transmitter doesn't work right
2. Receiver doesn't work right
3. Theory is imperfect
4. System architecture isn't right

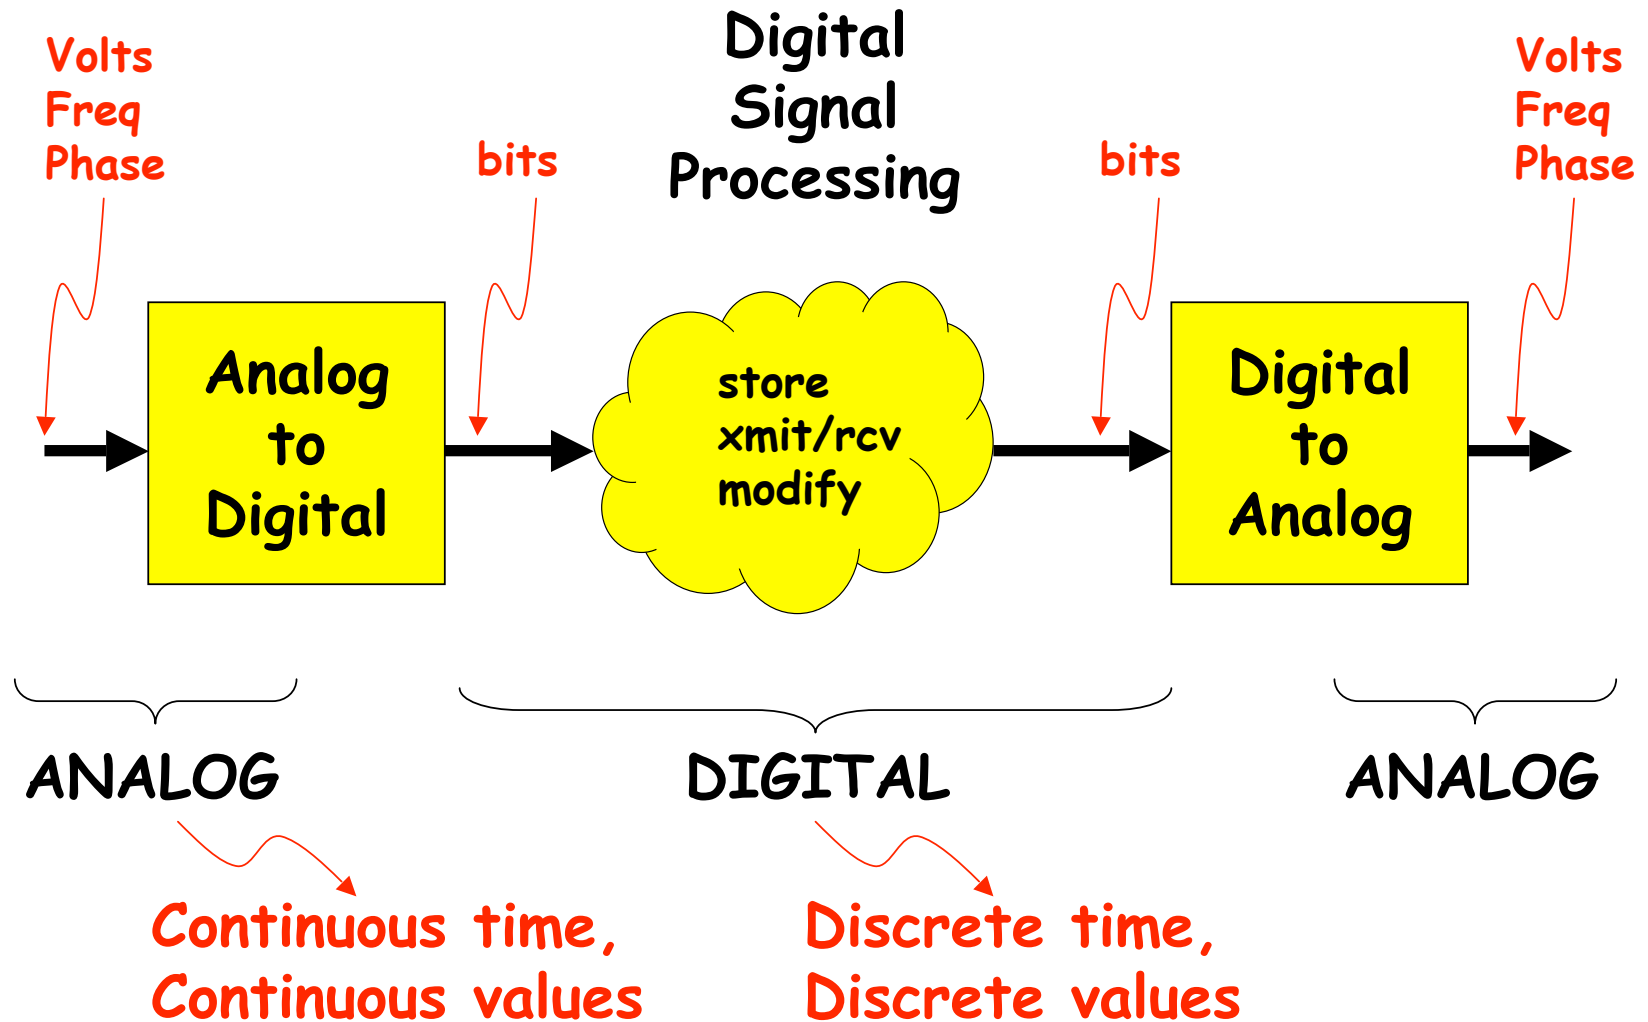

- **Answer:** All of the above!

- Noise, transmitter/receiver imperfections **inevitable**, so must **design system to tolerate** some amount of error

Analog communications issues

- **Problem:** It's hard to **distinguish legitimate analog waveforms from corrupted** ones
 - Every waveform is potentially legitimate!
- Small errors accumulate at each hop
- Endpoints can't help, so need to **eliminate errors at each hop**

Plan: *Mixed Signal Architecture*

Discrete time, Discrete values

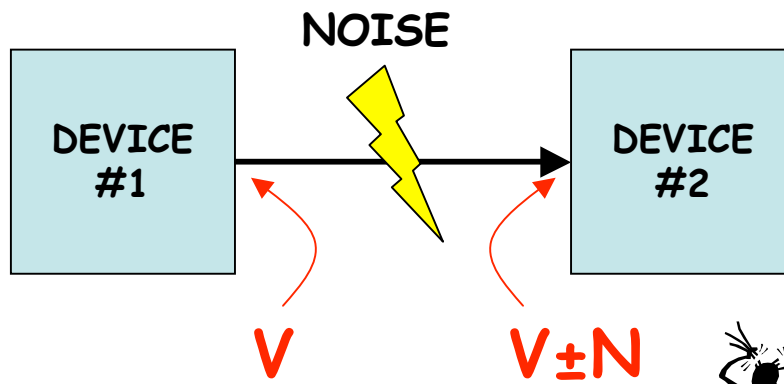

- Continuous-time, **continuous-valued waveform** is being converted into a **discrete-valued sequence**
 - **Only certain values** are "allowed" to be used
- Questions yet to be answered:
 1. **How many discrete values** should we use?
 2. **How rapidly in time** should we sample the waveform?

Digital signaling

- First encoding attempt:

- But, what happens in the **presence of noise**?

So an output voltage just below V_L might become an illegal input voltage in the forbidden zone!

Big Idea: Noise Margins

Let's leave room for bad things to happen! So we'll design devices restore marginally valid input signals. They must accept marginal inputs and provide unquestionable outputs (i.e., to leave room for noise).

INPUTS:

Noise Margins

How many discrete values?

Quantization Error

- Introduce **at most $\frac{1}{2}$ interval length** of quantization error

Need for Continuous to Discrete Conversion

Real world (Hack RF)

$x_c(t)$

A-to-D Converter

Computer (Python)

$x[n]$

$x[n]$

1

- The boundary between analog and digital
 - Real world filled with continuous-time signals
 - Computers operate on **discrete-time sequences**
- Crossing the analog to digital boundary requires **conversion between the two**

Modelling Continuous-to-Discrete Conversion

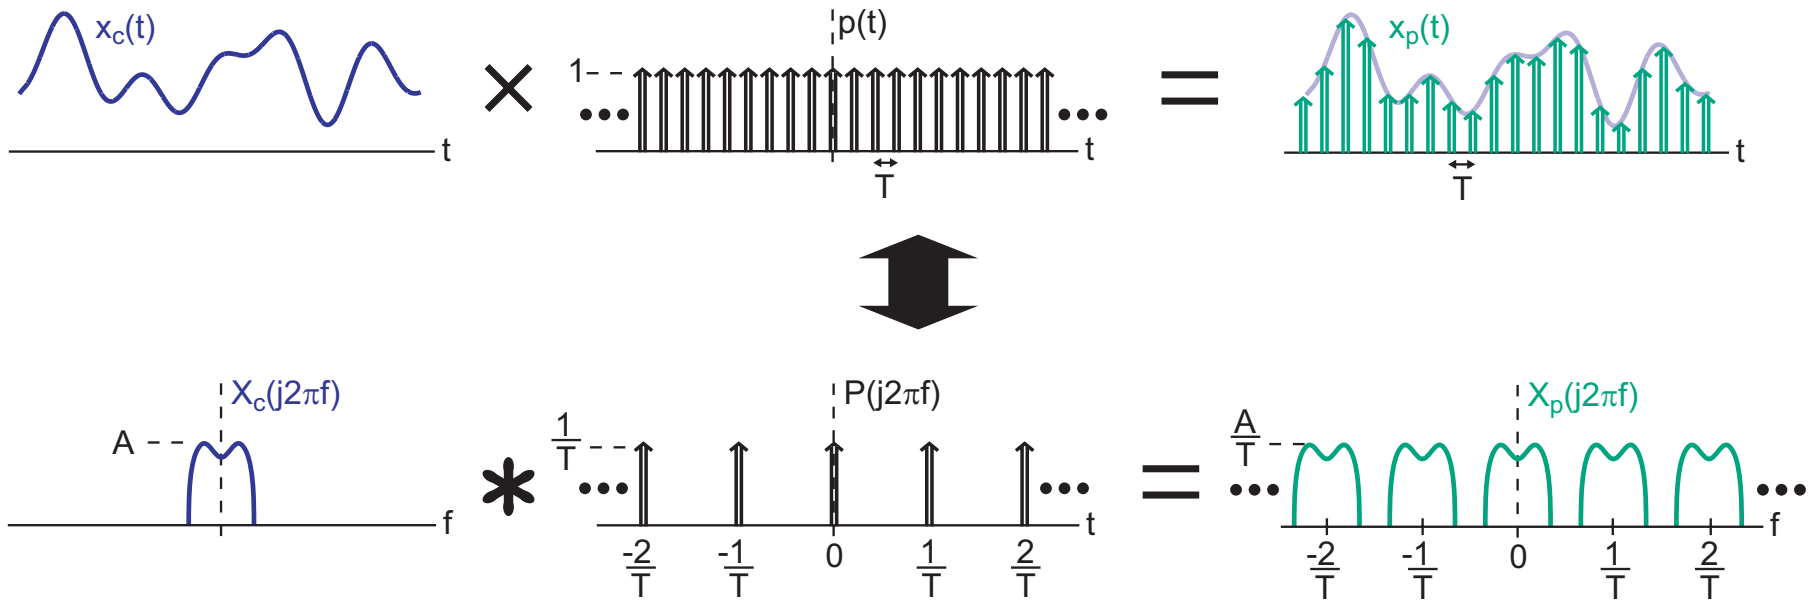

- Two-step process:
 1. Sample continuous-time signal every T seconds
 - Model as multiplication of signal with impulse train
 2. Create sequence from amplitude of scaled impulses
 - Model as rescaling of time axis ($T \rightarrow 1$)

Fourier Transform of Impulse Train

- Impulse train in time corresponds to **impulse train in frequency**
 - Spacing in time of **T seconds** corresponds to **$1/T$ Hz** spacing in frequency

Frequency Domain view of Sampling

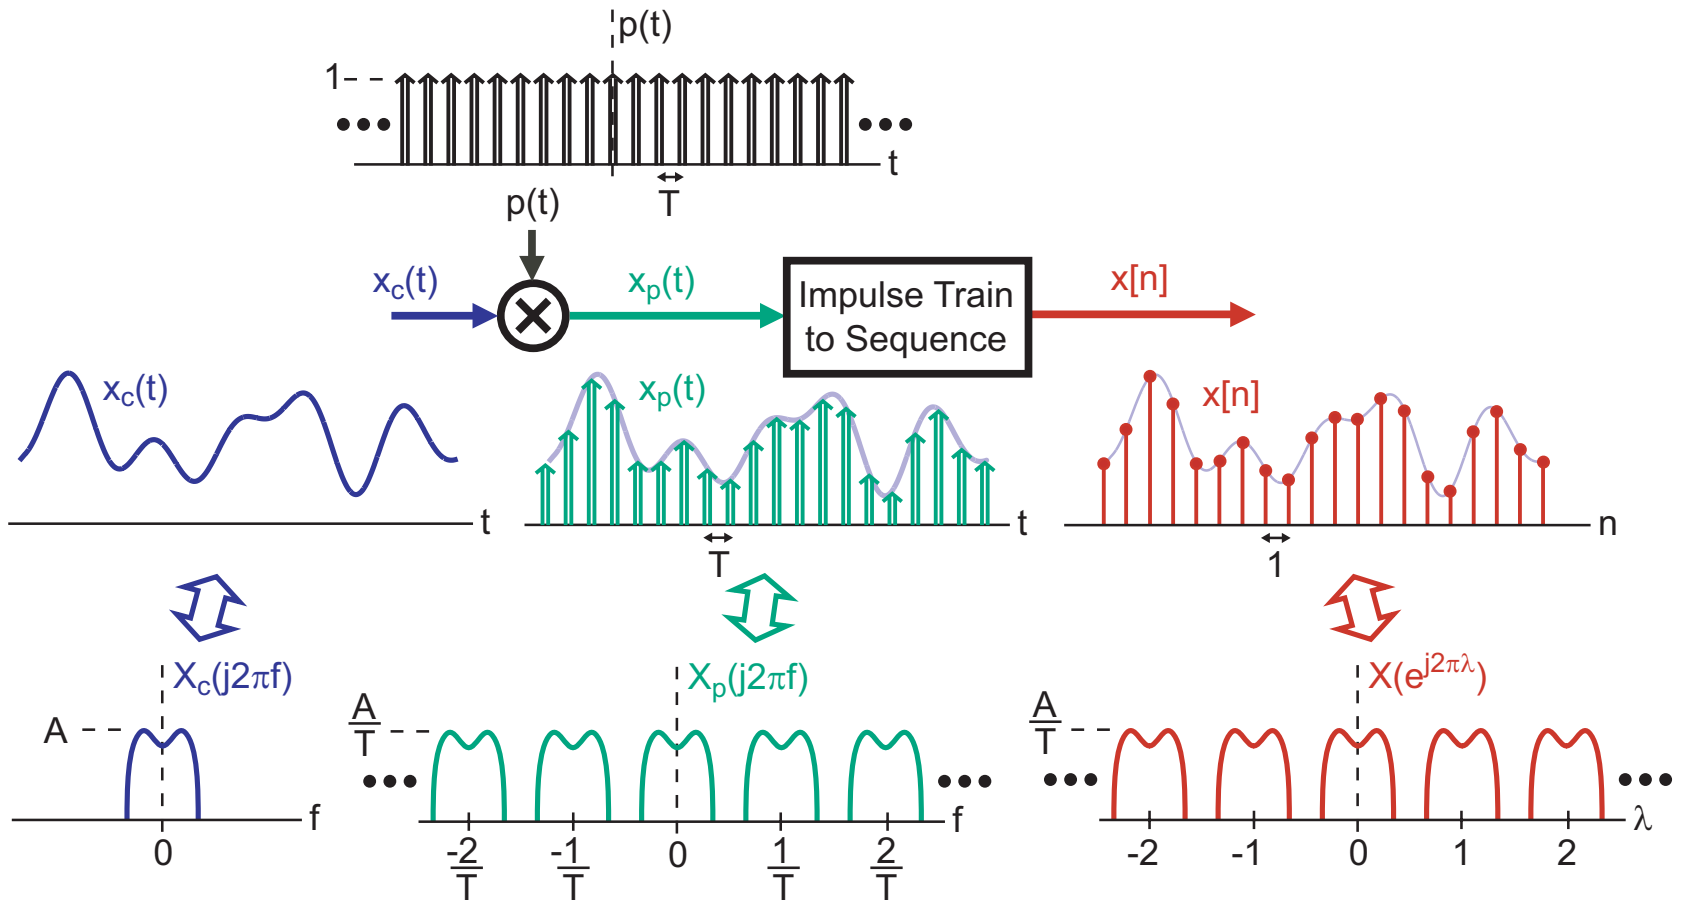

- Sampling in time leads to a **periodic Fourier Transform**, with period $1/T$

Frequency Domain View of a Sequence

- Conversion to sequence **amounts to $T = 1$**
- Resulting Fourier Transform now periodic with period 1

Summary of Continuous-to-Discrete Conversion

- Sampling leads to periodicity in frequency domain

The Sampling Theorem

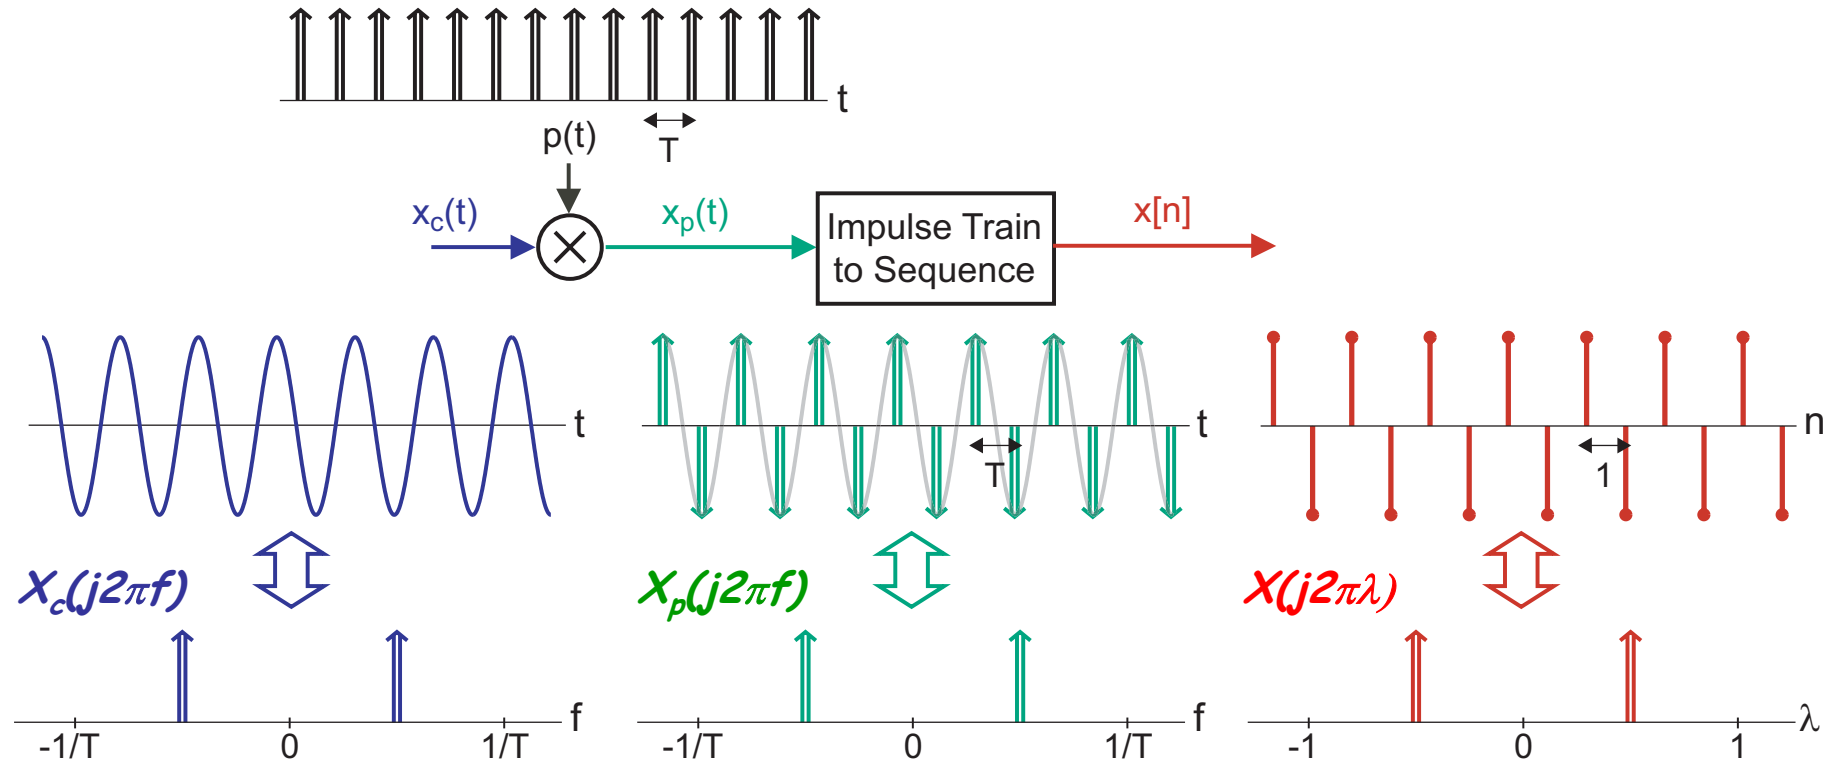

- **No overlap in frequency domain** (aliasing) when:
 - $1/T - f_{bw} \geq f_{bw}$ or $1/T \geq 2f_{bw}$
- We refer to the **minimum $1/T$ that avoids aliasing** as the **Nyquist sampling frequency** of a signal

Sine Wave Example: Sampling Above Nyquist Rate

- **Time domain:** Resulting sequence **maintains same period** as input signal

Sine Wave Example: Sampling at Nyquist Rate

- **Time Domain:** Resulting sequence **maintains same period** as input signal

Sine Wave Example: Sampling at Half the Nyquist Rate

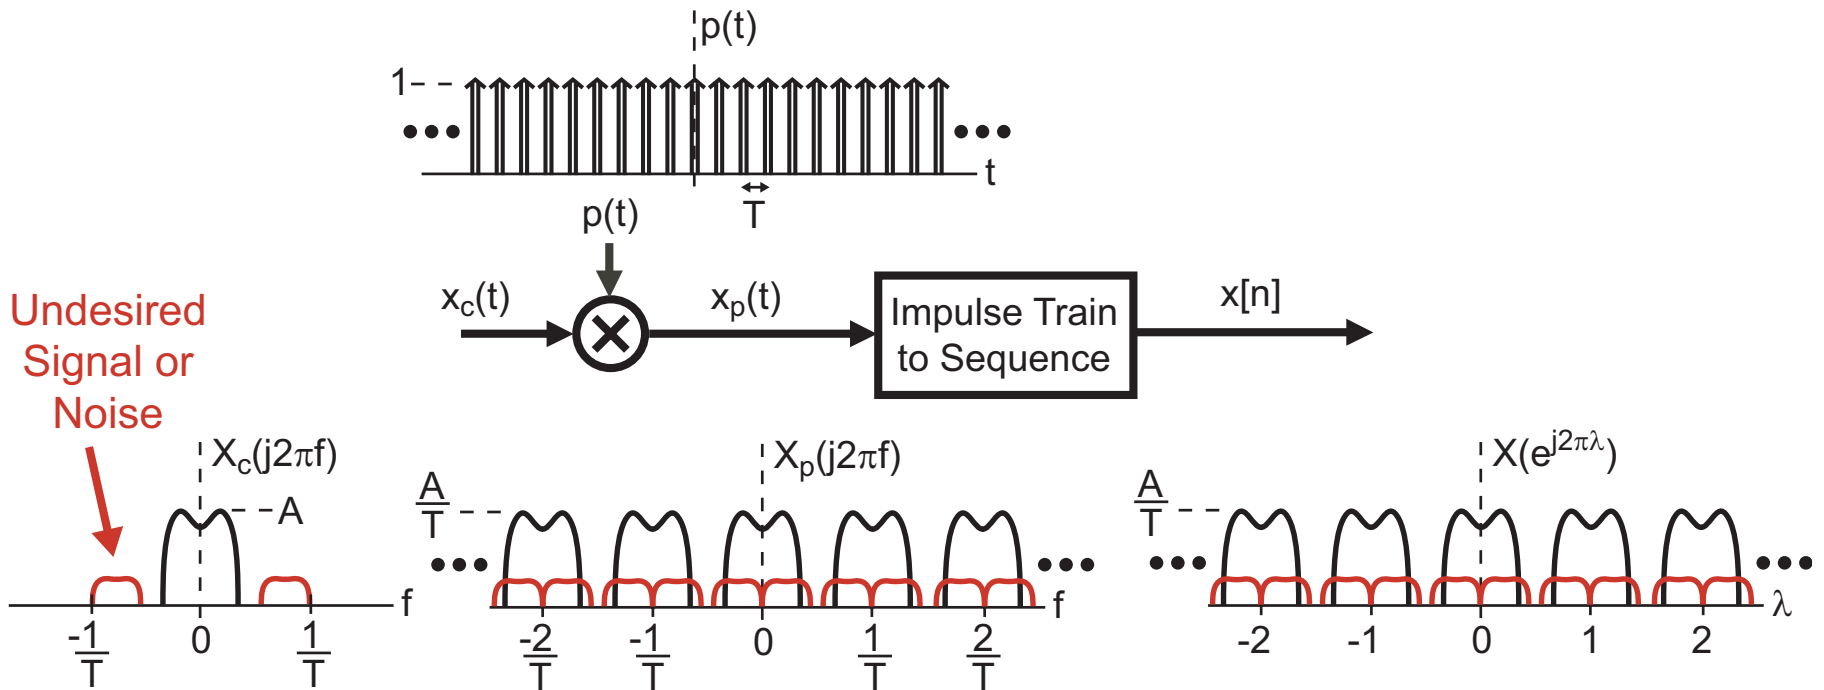

- Sequence now **appears as constant (zero frequency) signal**
- Frequency domain: **Aliasing to 0**

Sine Wave Example: Sampling Below the Nyquist Rate

- Resulting sequence is now a **sine wave with a different period than the input**
- Frequency domain: **Aliasing** to a lower frequency

The Issue of High Frequency Noise

- Typically **set sample rate to exceed desired signal's bandwidth**
- Real systems can introduce **noise/other interference at high frequencies**
 - Sampling causes **noise to alias** into desired frequency band

Anti-Alias Filtering

- Practical A/D converters **include a continuous-time filter** before the sampling operation
 - Designed to **filter out noise and interference above $1/2T$** in frequency, **prevent aliasing**

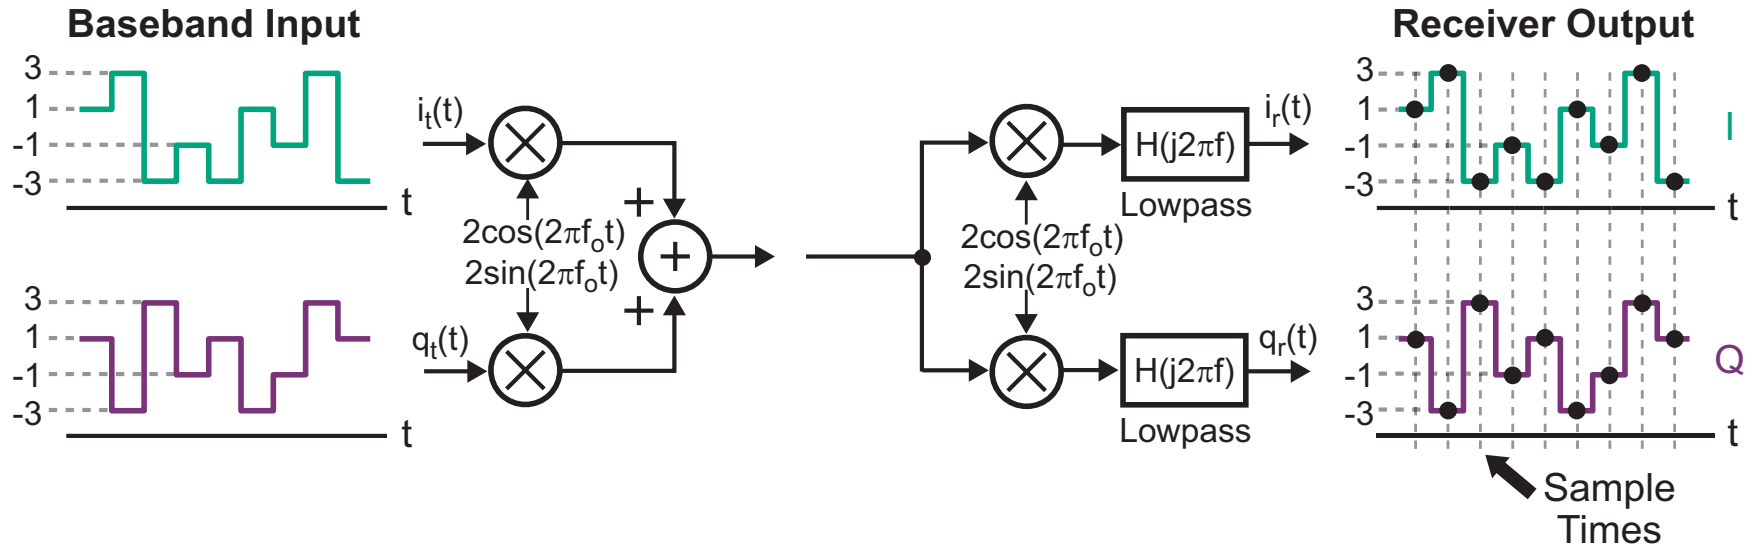

Summary: Advantages of Going Digital

- Allows **error correction** to be achieved
 - Less sensitivity to radio channel imperfections
- **Enables compression** of information
 - More efficient use of the channel
- Supports a **wide variety of information** content
 - Voice, text, video can all be represented as digital bit streams

Roadmap

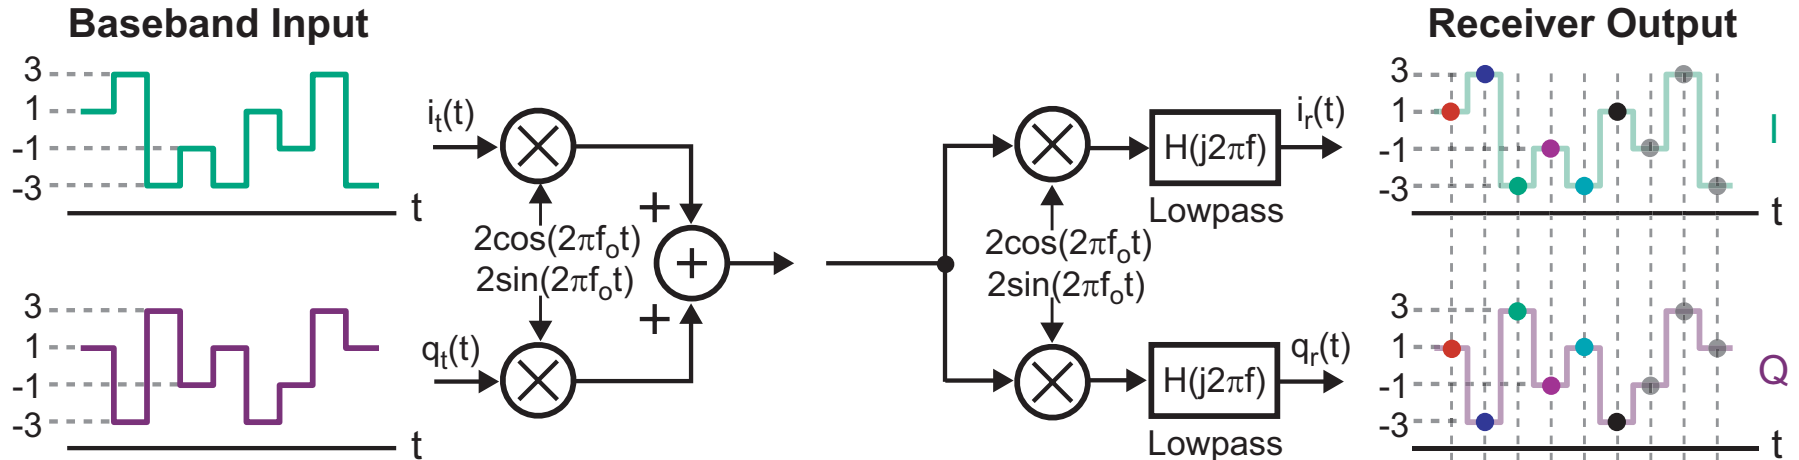

1. Analog I/Q modulation
2. Discrete-time processing of continuous signals
- 3. Digital I/Q Modulation**

Digital I/Q modulation

- Leverage analog communication channel to send **discrete-valued symbols**
 - **Example:** Send symbol from set $\{-3, -1, 1, 3\}$ on both I and Q channels
- At receiver, **sample I/Q waveforms** every **symbol period**
 - Associate each sampled I/Q value with symbols from same set on both I and Q channels

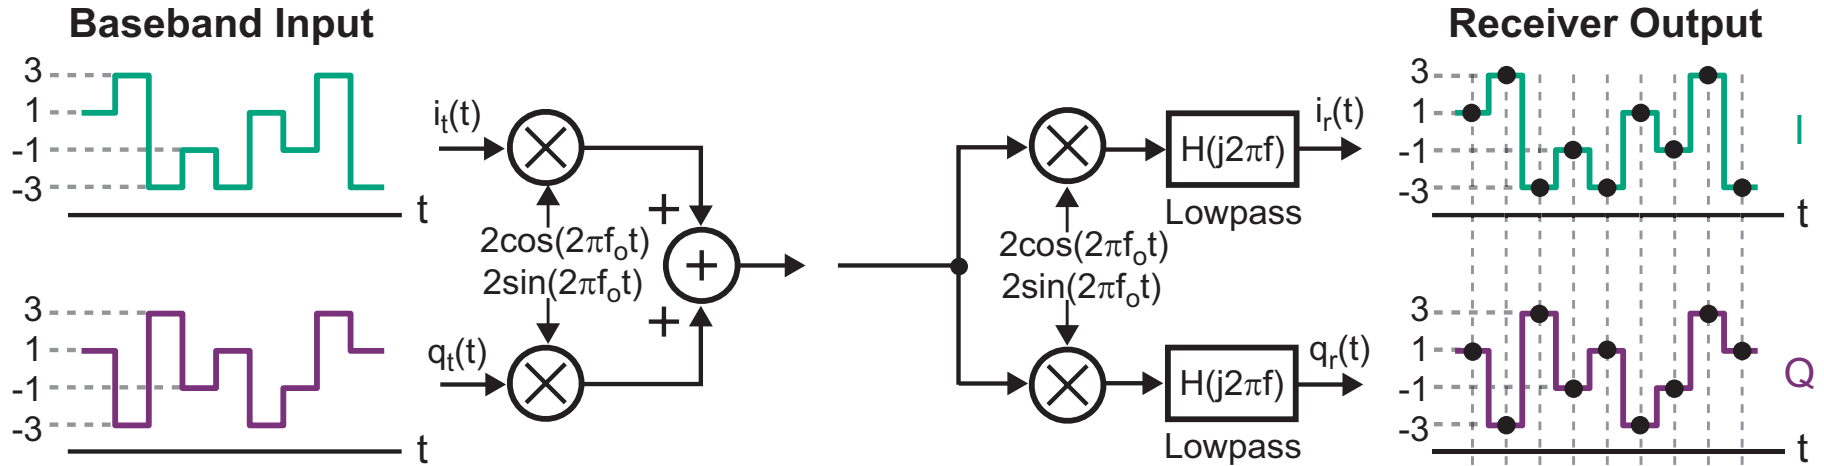

Constellation Diagrams

- **Plot I/Q samples on x-y axis**
 - As samples are plotted, constellation diagram eventually displays all possible symbol values
- Provides a sense of **how easy it is to distinguish** between different symbols

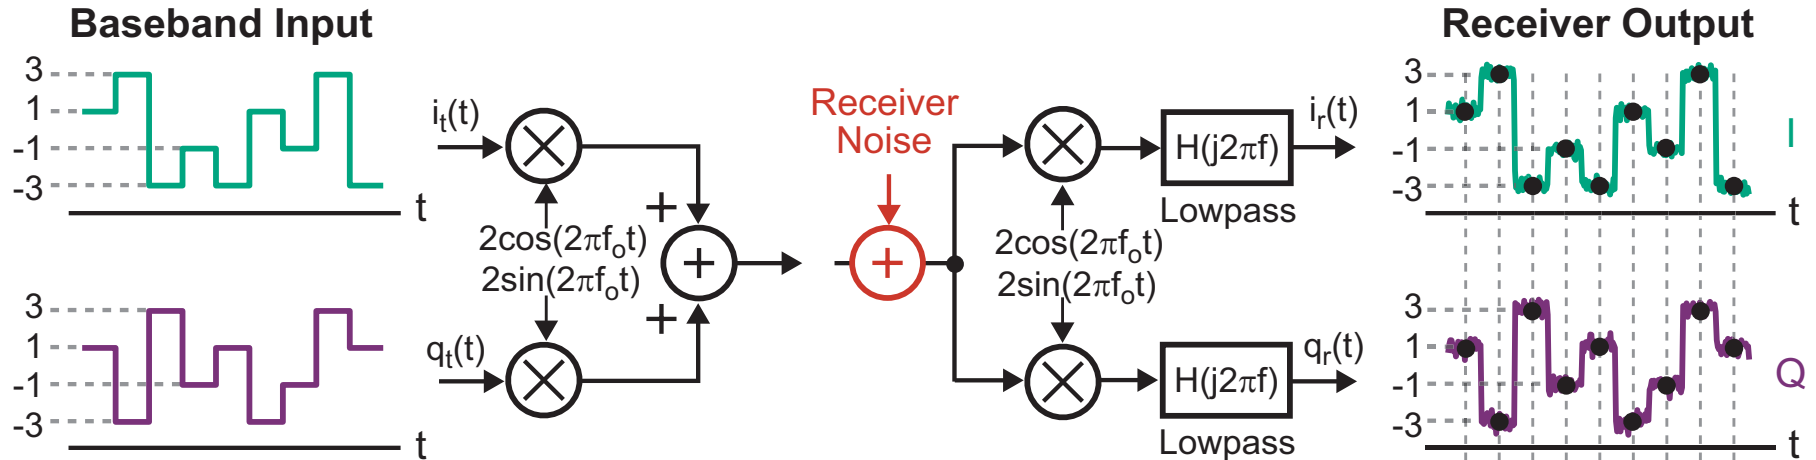

Sending Digital Bits

- **Assign bits to each I/Q symbol**
 - **Example:** I/Q = {1, 3} translates to bits 1110
 - **Gray coding** minimizes bit errors when symbol errors are made
 - **Example:** I/Q = {3, 3} translates to bits 1010 (one bit flip from {1, 3})

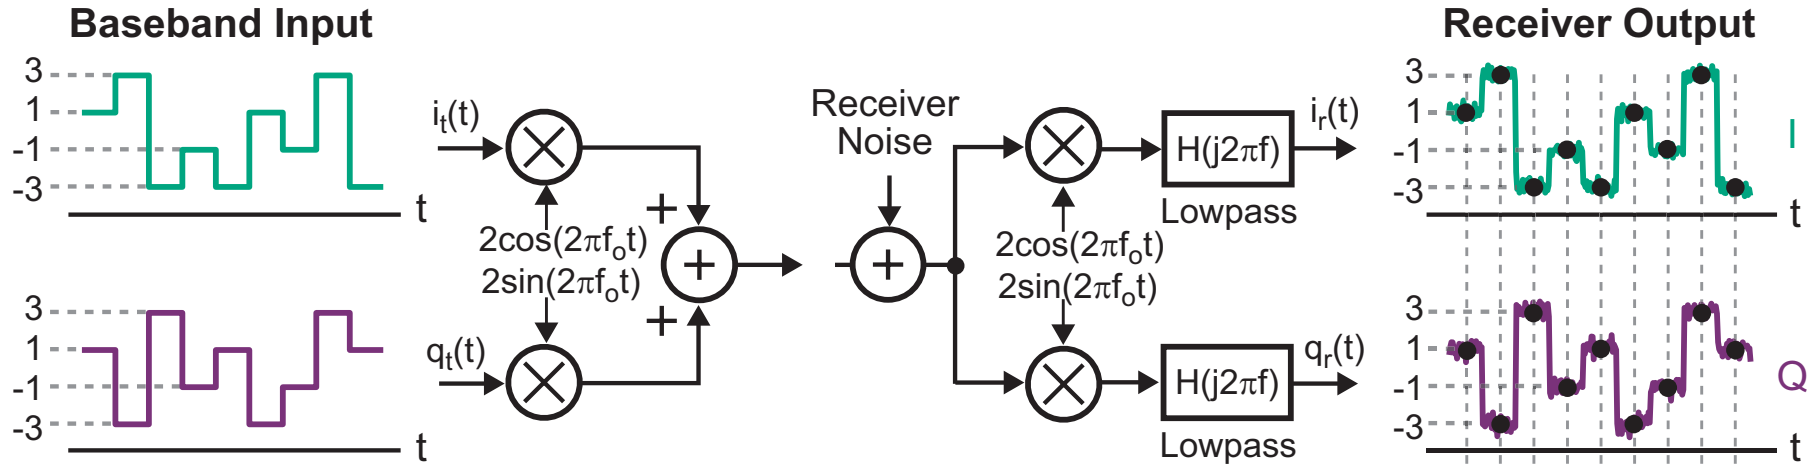

The Impact of Noise

- At receiver, **noise perturbs** sampled I/Q values
 - Constellation points no longer consist of single points for each symbol
- **Issue:** What's the **best way of matching** received **I/Q samples** with their corresponding transmitted symbols?

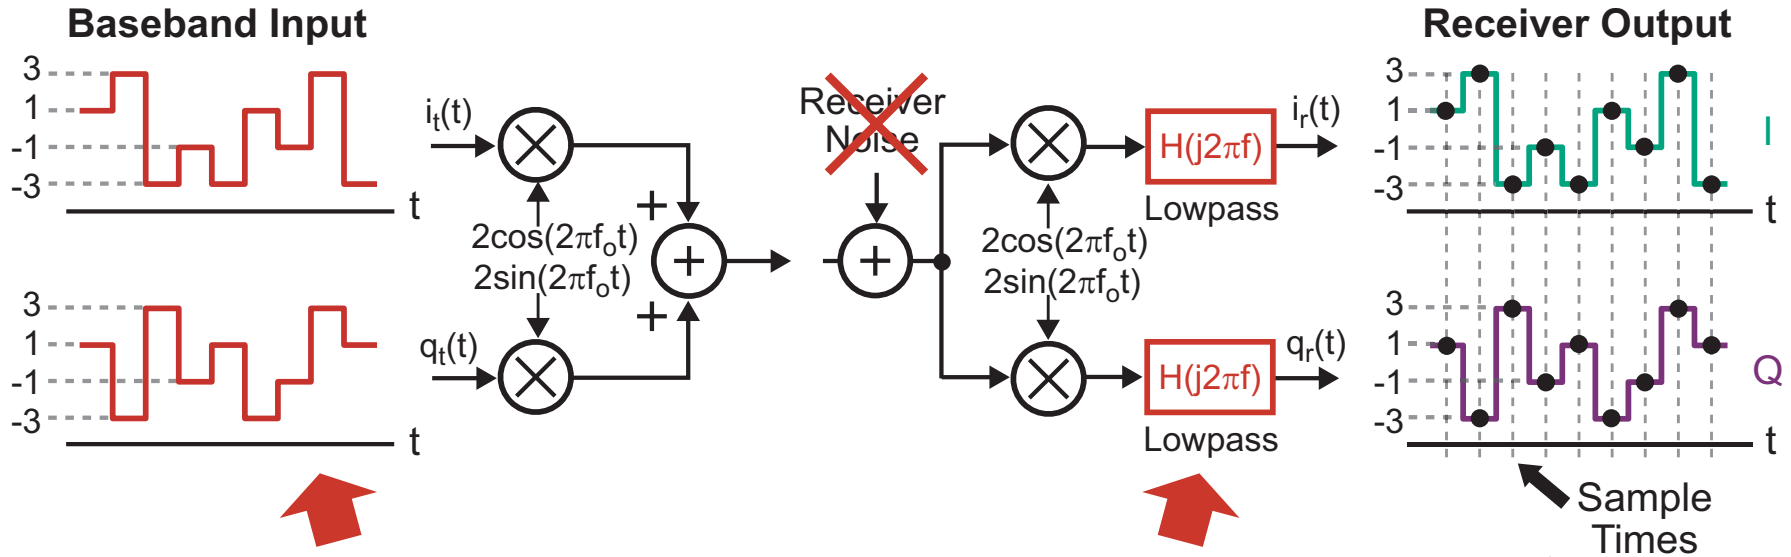

Symbol Selection based on Slicing

- Receiver matches I/Q samples to corresponding symbols based on **decision regions** comprised of decision boundaries
 - Choose decision boundaries to minimize symbol errors
- Decision boundaries also called **slicing levels**

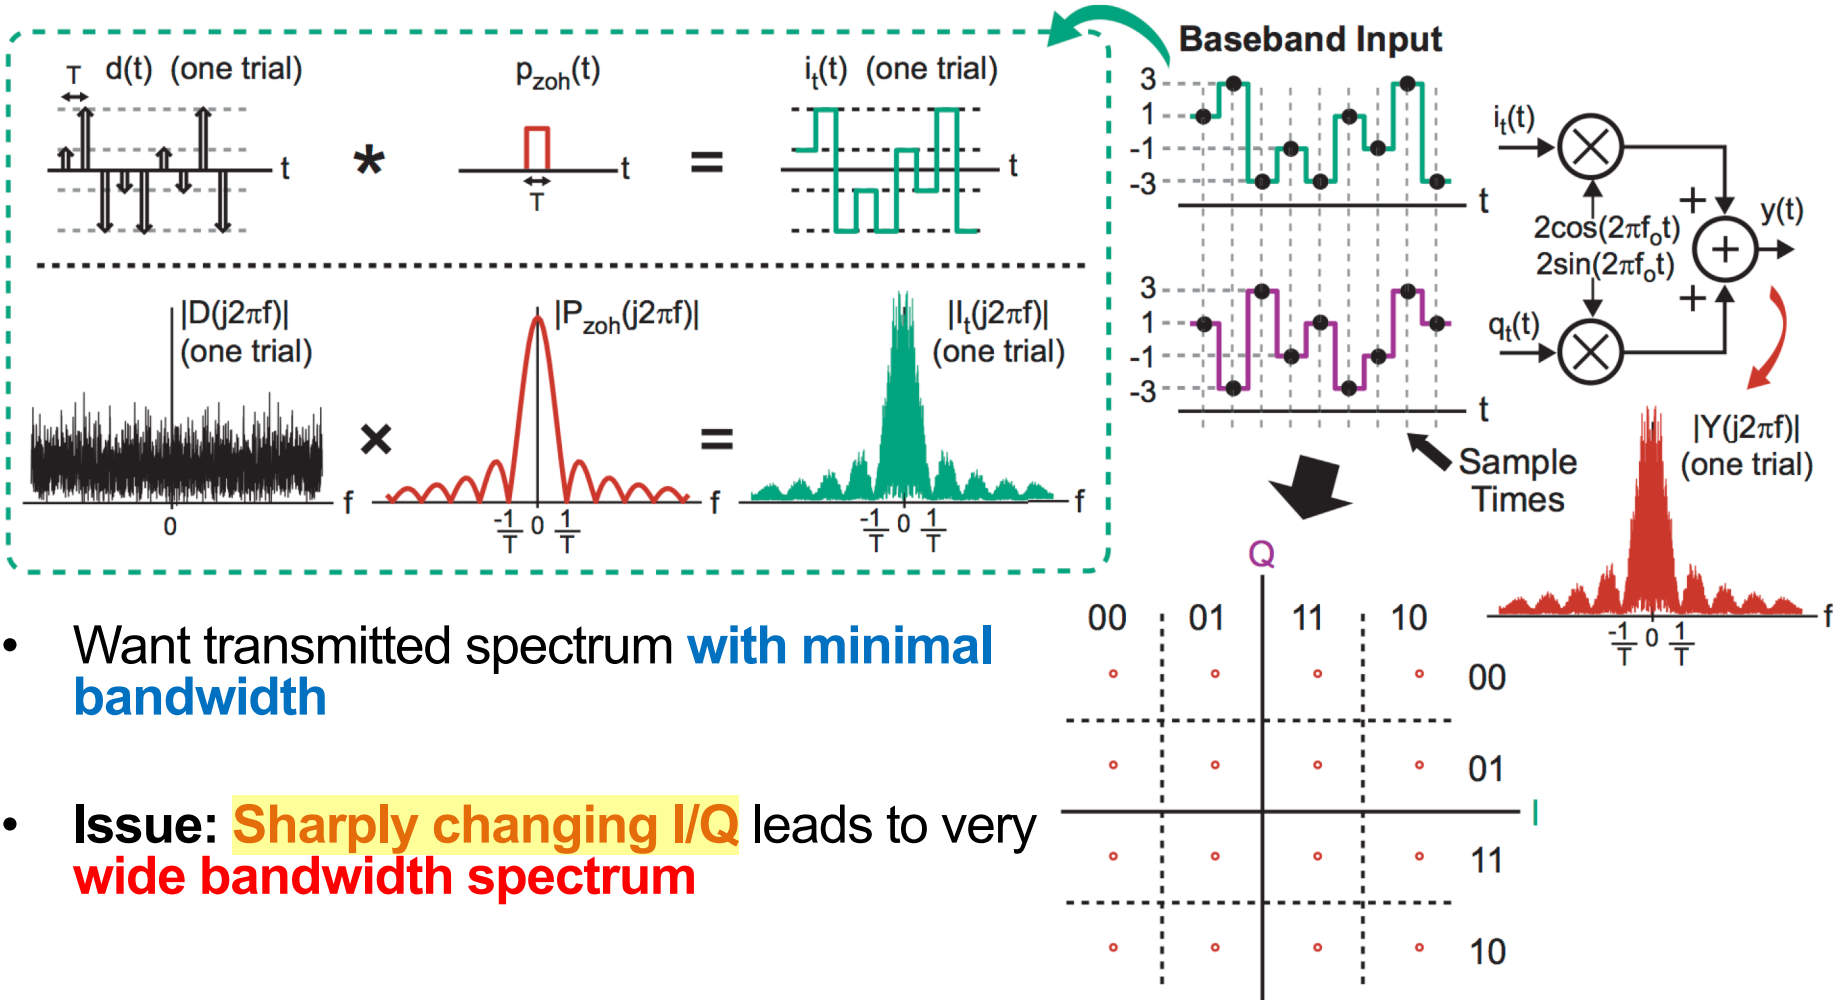

Transitioning Between Symbols

- Transition behavior influenced by transmit I/Q input waveforms **and** receive filter
 - **Today:** Focus on **what the transmitter does**
 - **Ignore impact of noise** for this analysis

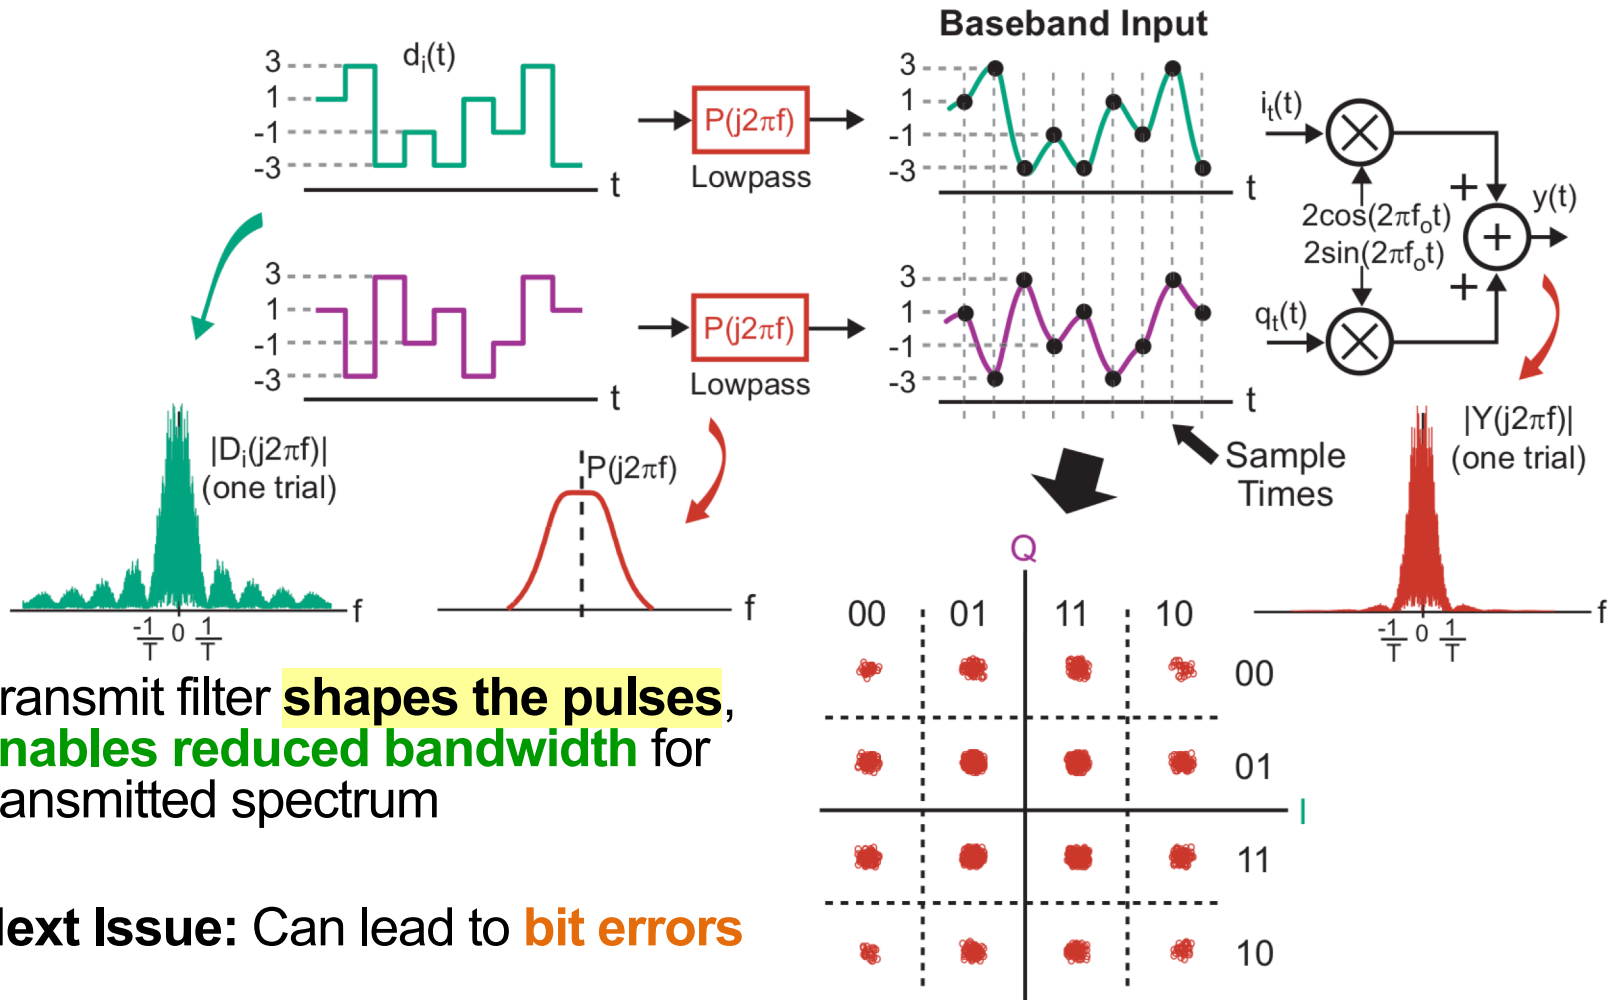

Transitions and the Transmitted Spectrum

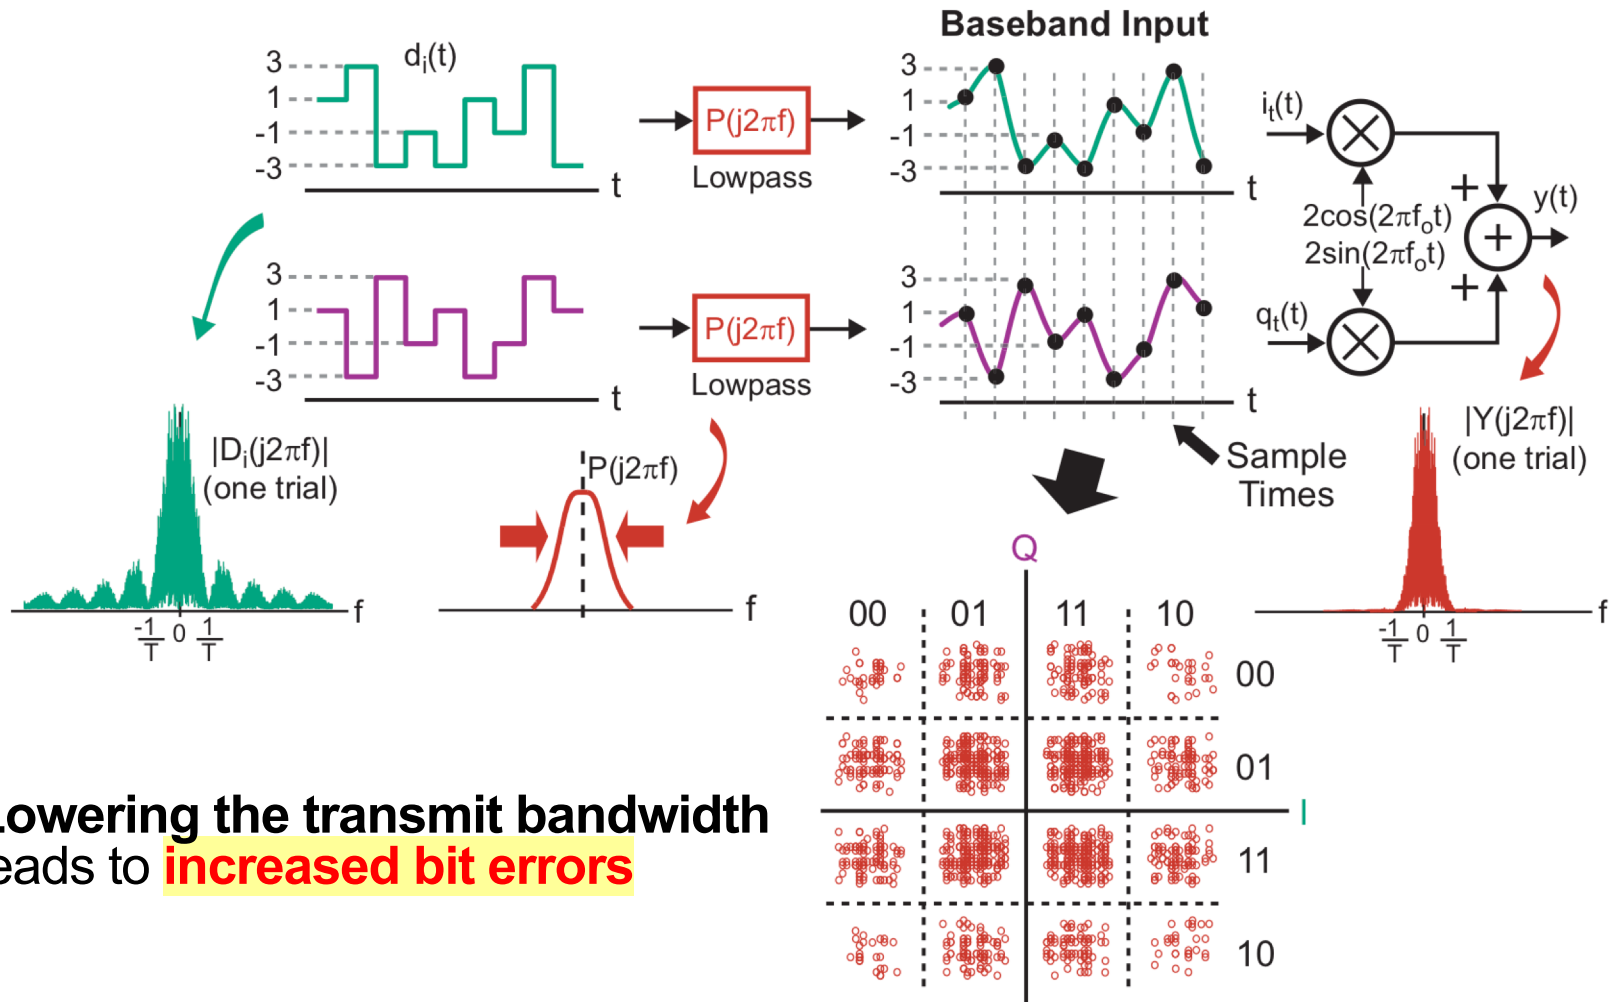

- Want transmitted spectrum **with minimal bandwidth**
- **Issue:** **Sharply changing I/Q** leads to very **wide bandwidth spectrum**

Impact of Transmit Filter

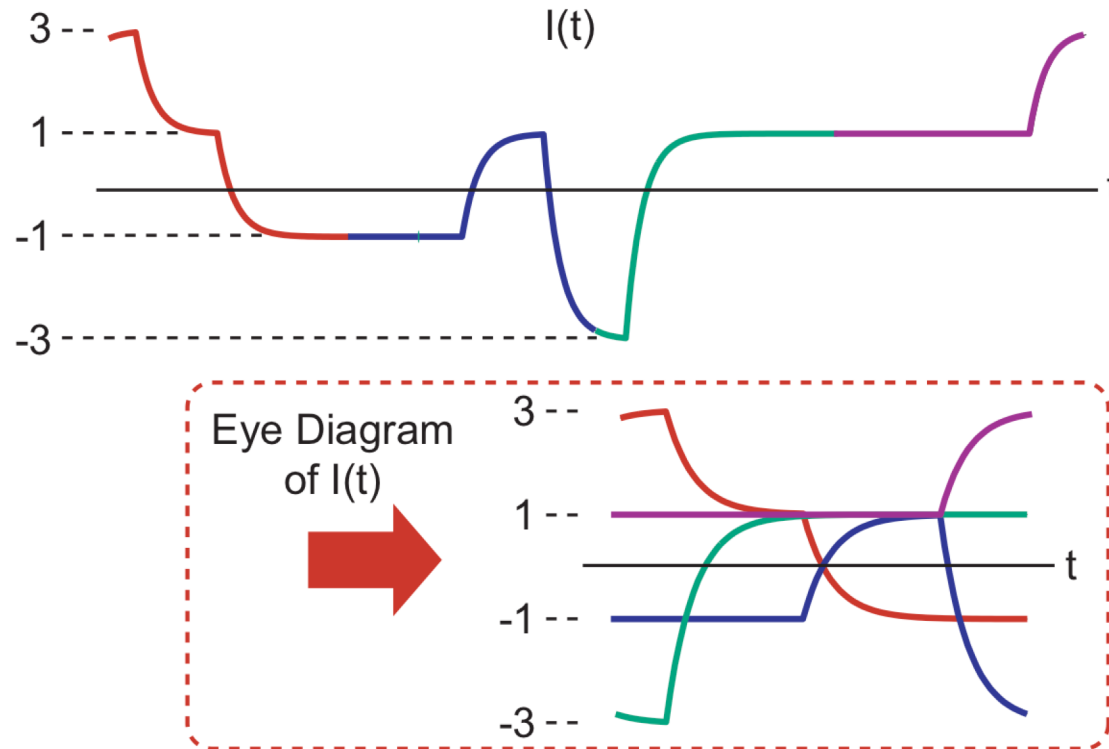

- Transmit filter **shapes the pulses**, **enables reduced bandwidth** for transmitted spectrum
- **Next Issue:** Can lead to **bit errors**

Impact of Low Bandwidth Transmit Filter

- Lowering the transmit bandwidth leads to **increased bit errors**

Eye Diagrams

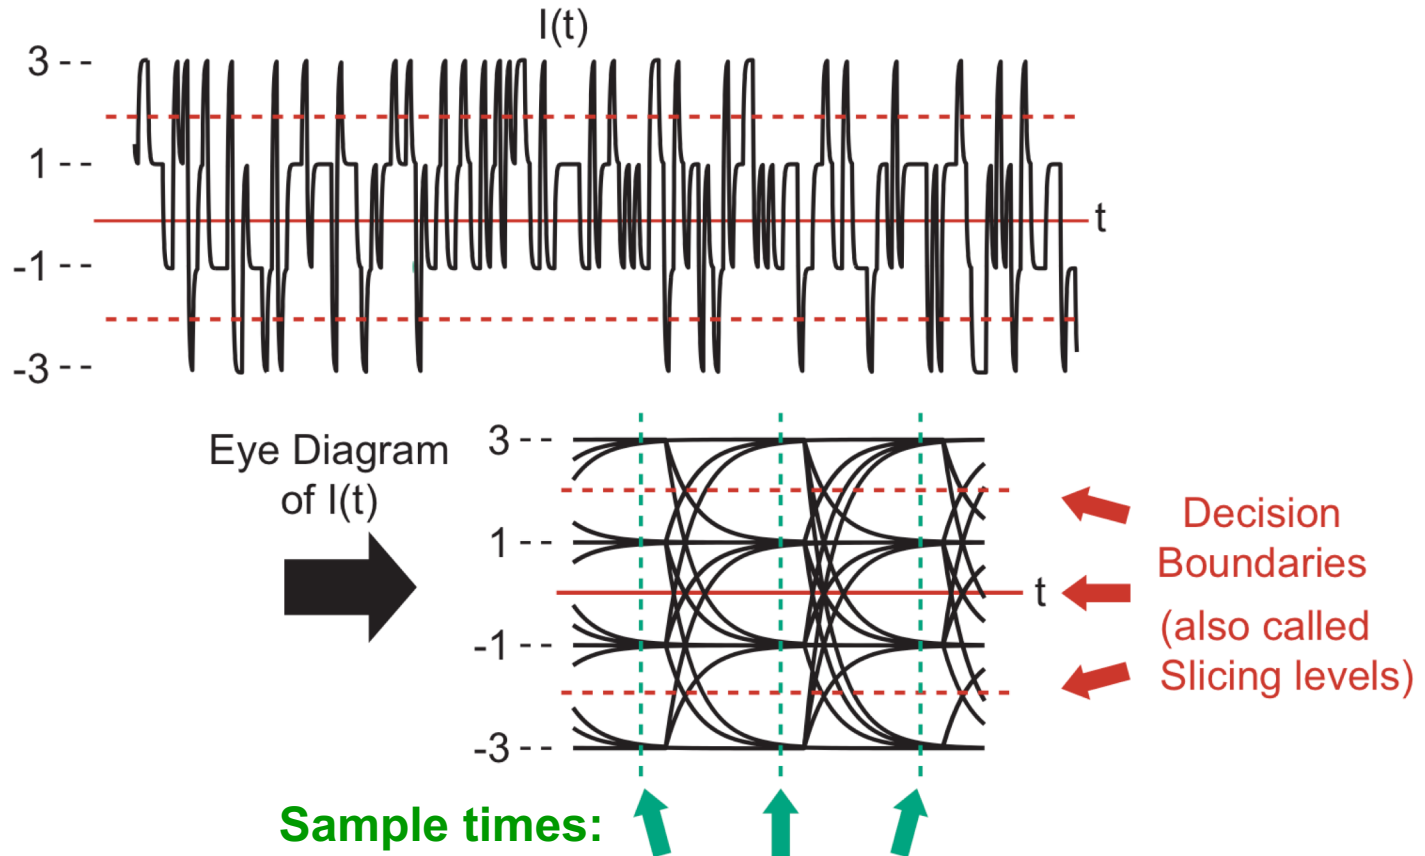

- **Eye Diagram:** Wrap signal back onto itself in periodic time intervals, retaining all “traces”

Looking at Many Symbols

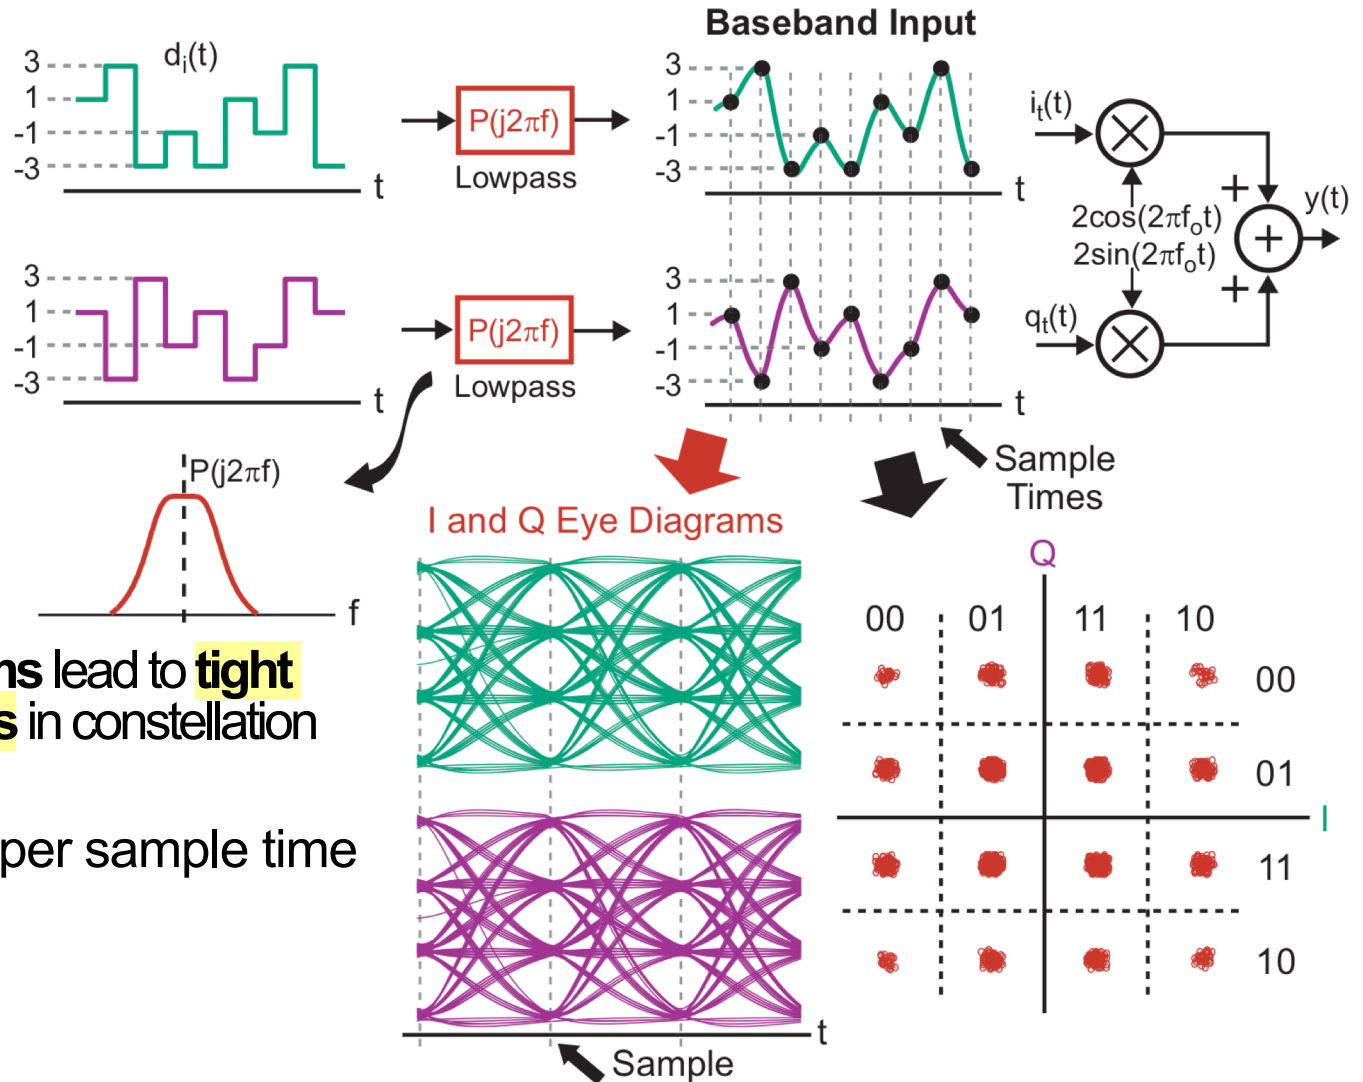

- Increasing the number of symbols eventually **reveals all possible symbol transition trajectories**
 - Intuitively **displays the impact of filtering** on transmitted signal

Assessing the Quality of an Eye Diagram

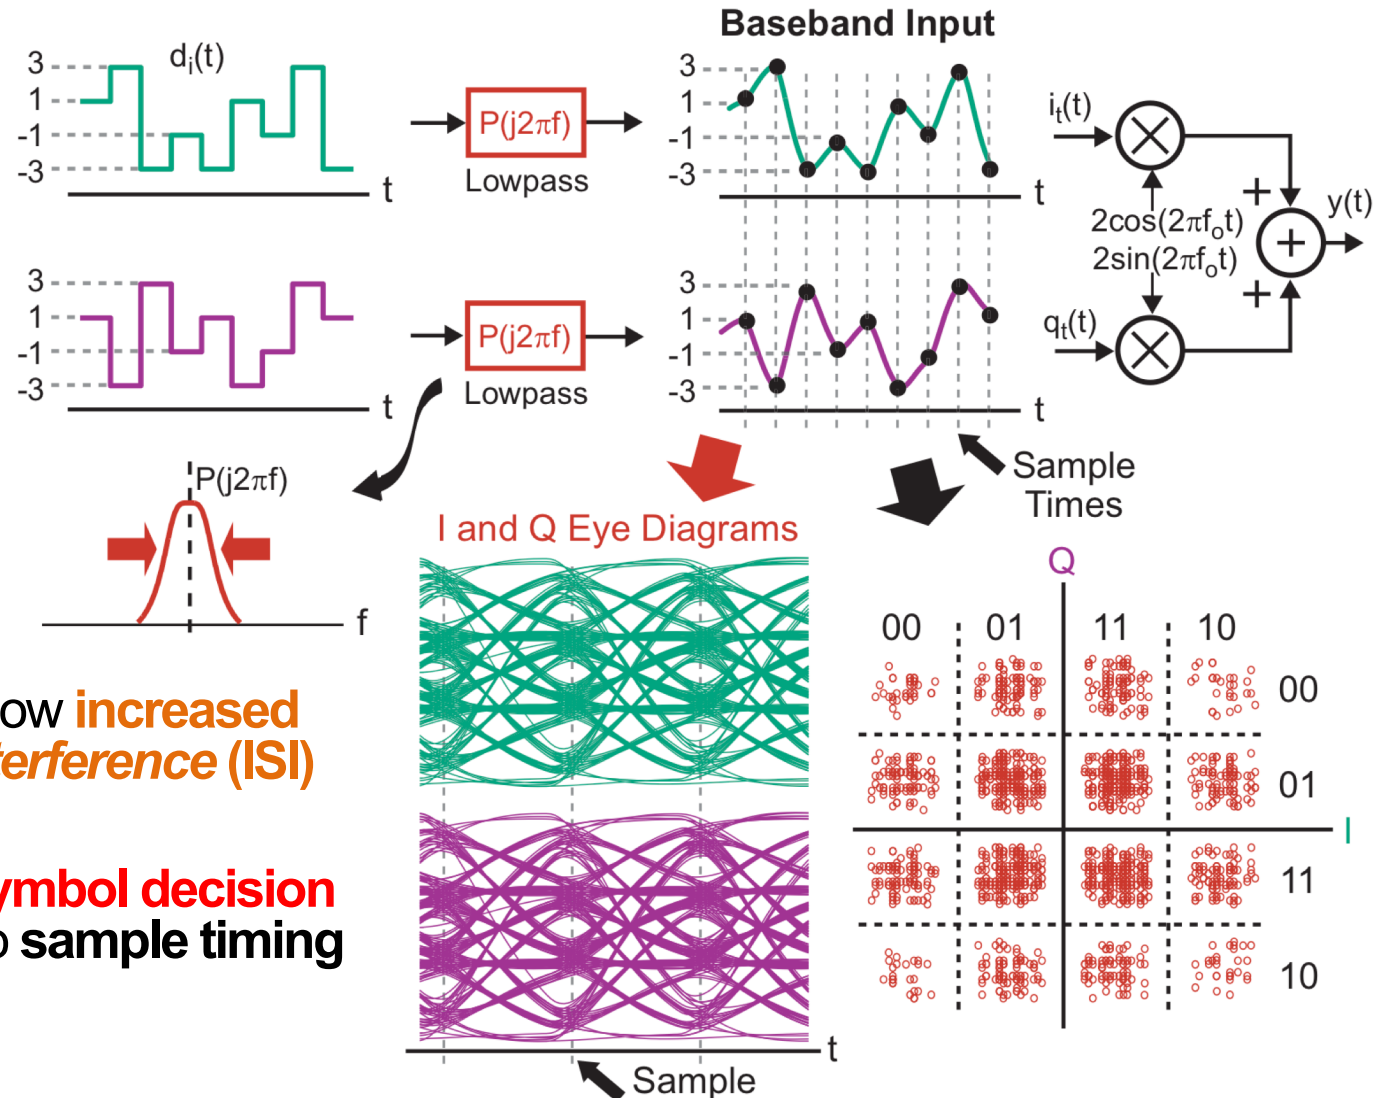

- Eye diagram **allows visual inspection of the impact of sample time and decision boundary choices**
 - **Large “eye opening”** implies less vulnerability to symbol errors

Relating Eye Diagrams to Constellation

- **Open eye diagrams** lead to **tight symbol groupings** in constellation
 - Assumes proper sample time placement

Impact of Low Transmit Bandwidth

- Eye diagrams show **increased inter-symbol interference (ISI)**
 - Also show **symbol decision sensitivity** to **sample timing placement**

Digital Modulation: Summary

- **Digital modulation:** Sends **discrete-valued symbols** through an **analog** communication channel
 - Receiver must **sample** I/Q signals at the appropriate time
 - Receiver matches I/Q sample values to corresponding symbols based on **decision regions**
 - **Constellation diagrams** are a convenient tool to see likelihood of bit errors being made
- **Choice of transmit filter:** **Tradeoff** between achieving a **minimal bandwidth** transmitted spectrum and **minimal ISI**
 - **Eye diagrams:** A convenient tool to see effects of ISI and sensitivity of bit errors to sample time choice
