https://algs4.cs.princeton.edu

5.2 Tries

- *R-way tries*
- *ternary search tries*
- *character-based operations*

Summary of the performance of symbol-table implementations

Order of growth of the frequency of operations.

implementation	typical case			ordered operations	operations on keys
	search	insert	delete		
red-black BST	$\log n$	$\log n$	$\log n$	✔	`compareTo()`
hash table	1 †	1 †	1 †		`equals()` `hashCode()`

† under uniform hashing assumption

Q. Can we do better?

A. Yes, if we can avoid examining the entire key, as with string sorting.

String symbol table implementations cost summary

	character accesses (typical case)				dedup	
implementation	search hit	search miss	insert	space (references)	moby.txt	actors.txt
red-black BST	$L + c \lg^2 n$	$c \lg^2 n$	$c \lg^2 n$	$4n$	1.4	97.4
hashing (linear probing)	L	L	L	$4n$ to $16n$	0.76	40.6

n = number of string

L = length of string

R = radix

Challenge. Efficient performance for string keys.

String symbol table basic API

String symbol table. Symbol table specialized to string keys.

```
public class StringST<Value>

              StringST()                       create an empty symbol table
        void  put(String key, Value val)       put key–value pair into the symbol table
       Value  get(String key)                  return value paired with given key
        void  delete(String key)               delete key and corresponding value
                   ⋮                                       ⋮
```

Goal. Faster than hashing, more flexible than BSTs.

https://algs4.cs.princeton.edu

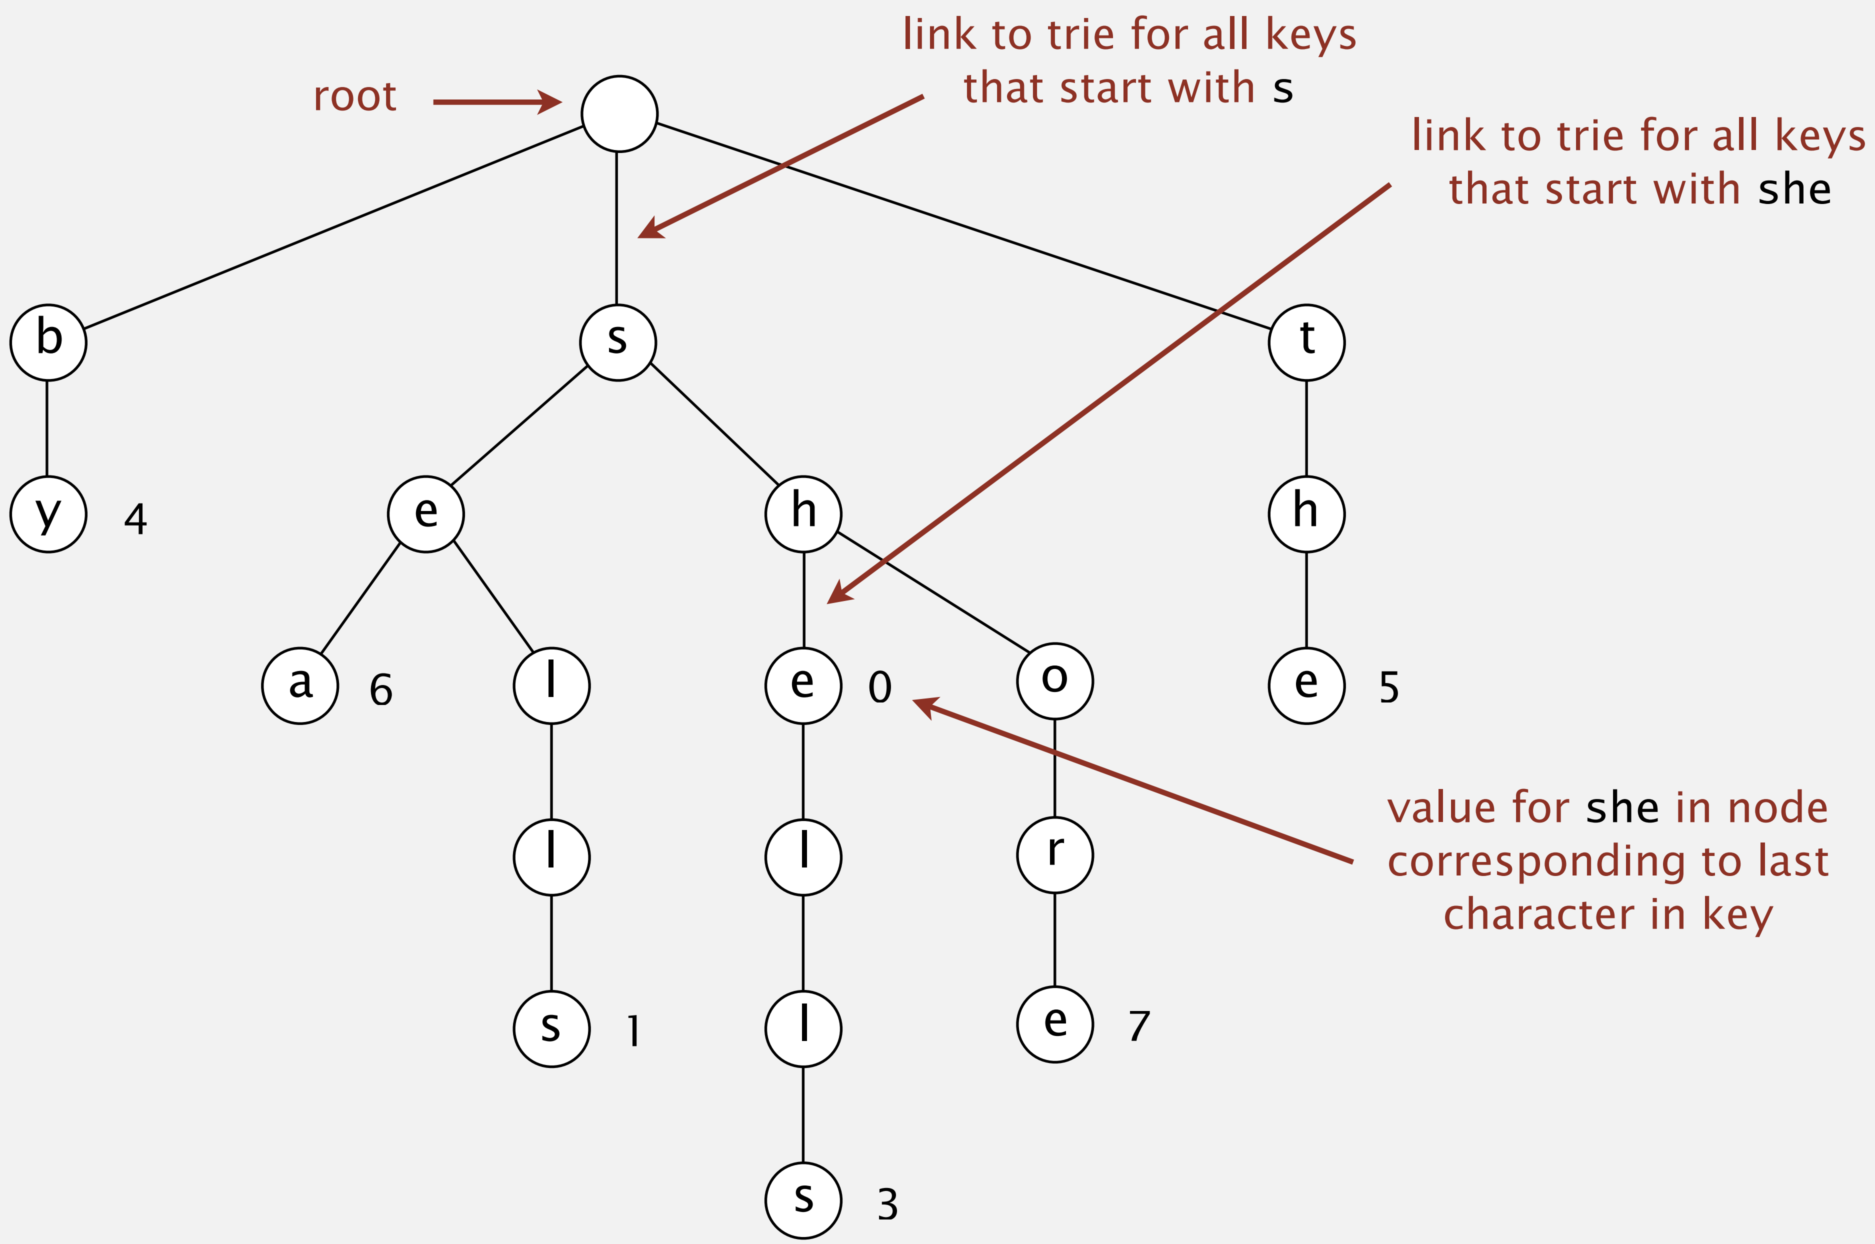
5.2 Tries

- *R-way tries*
- *ternary search tries*
- *character-based operations*

Tries

Tries. [from retrieval, but pronounced "try"]

- Store characters in nodes (not keys).
- Each node has R children, one for each possible character.
  (for now, we do not draw null links)



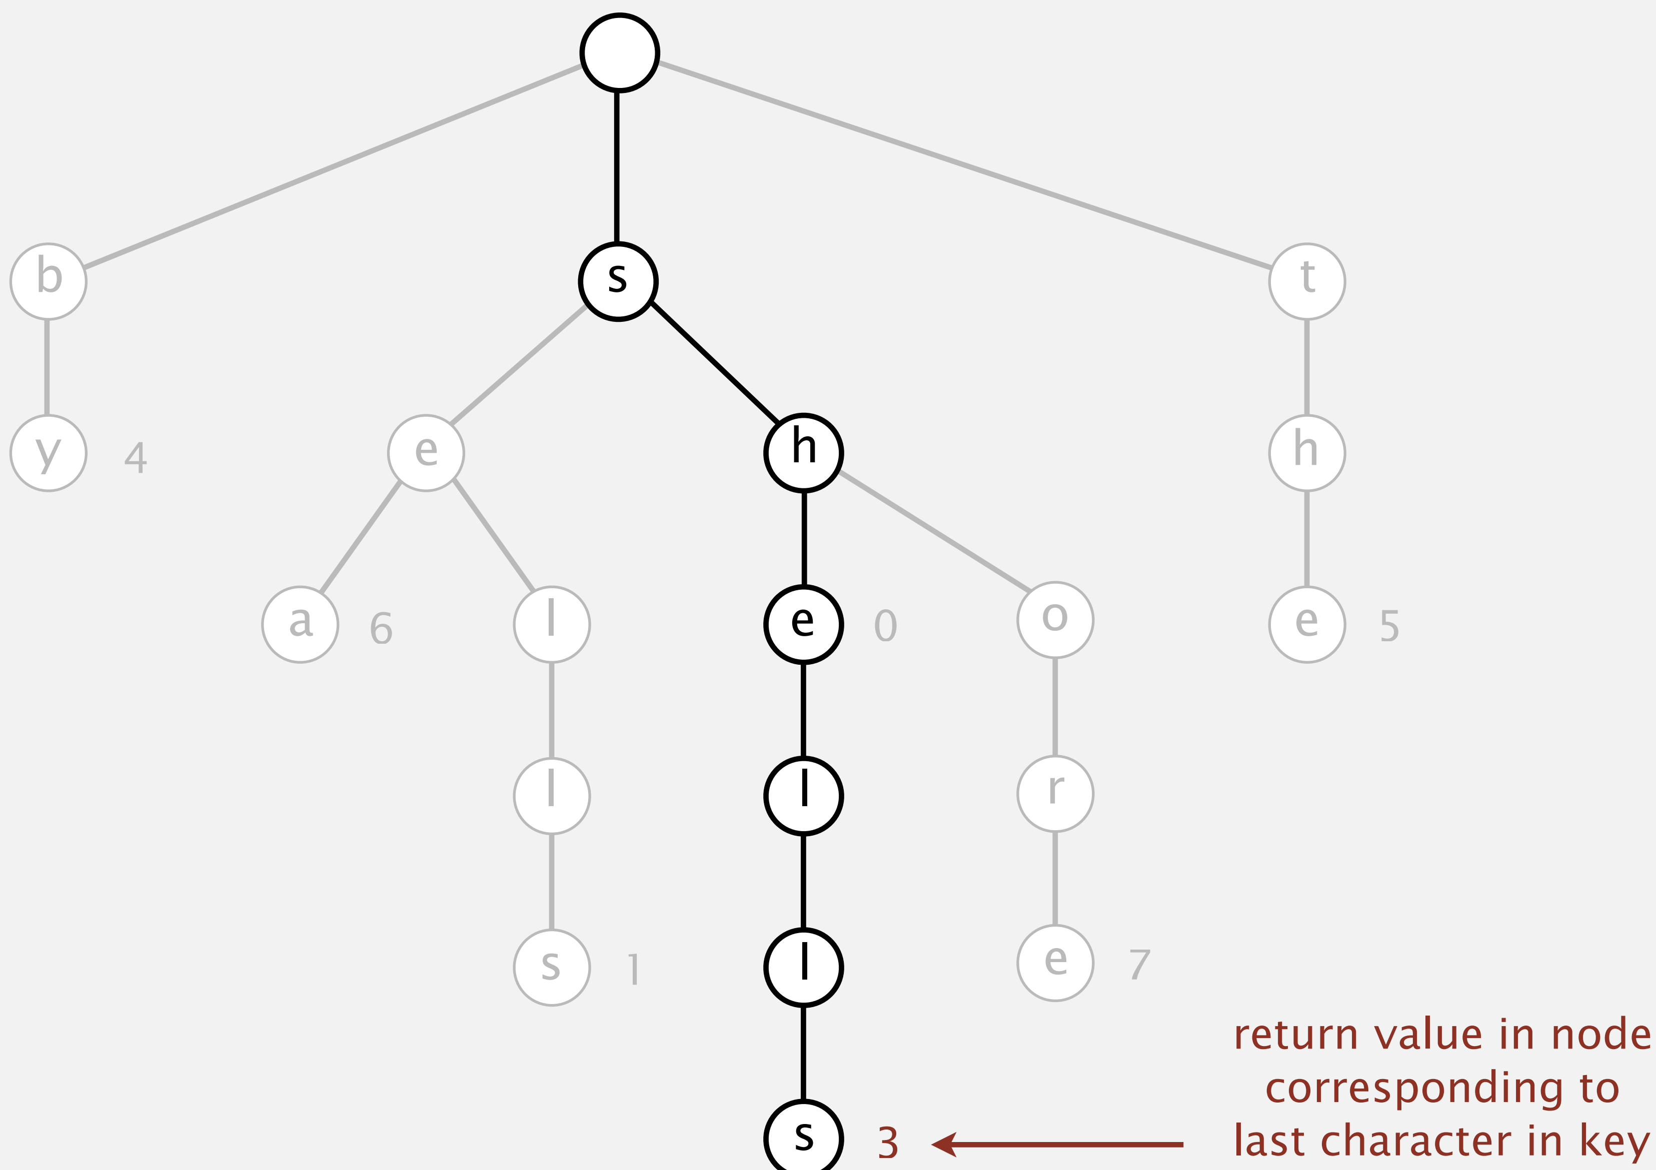
key	value
by	4
sea	6
sells	1
she	0
shells	3
shore	7
the	5

Search in a trie

Follow links corresponding to each character in the key.

- Search hit: node where search ends has a non-null value.
- Search miss: reach null link or node where search ends has null value.

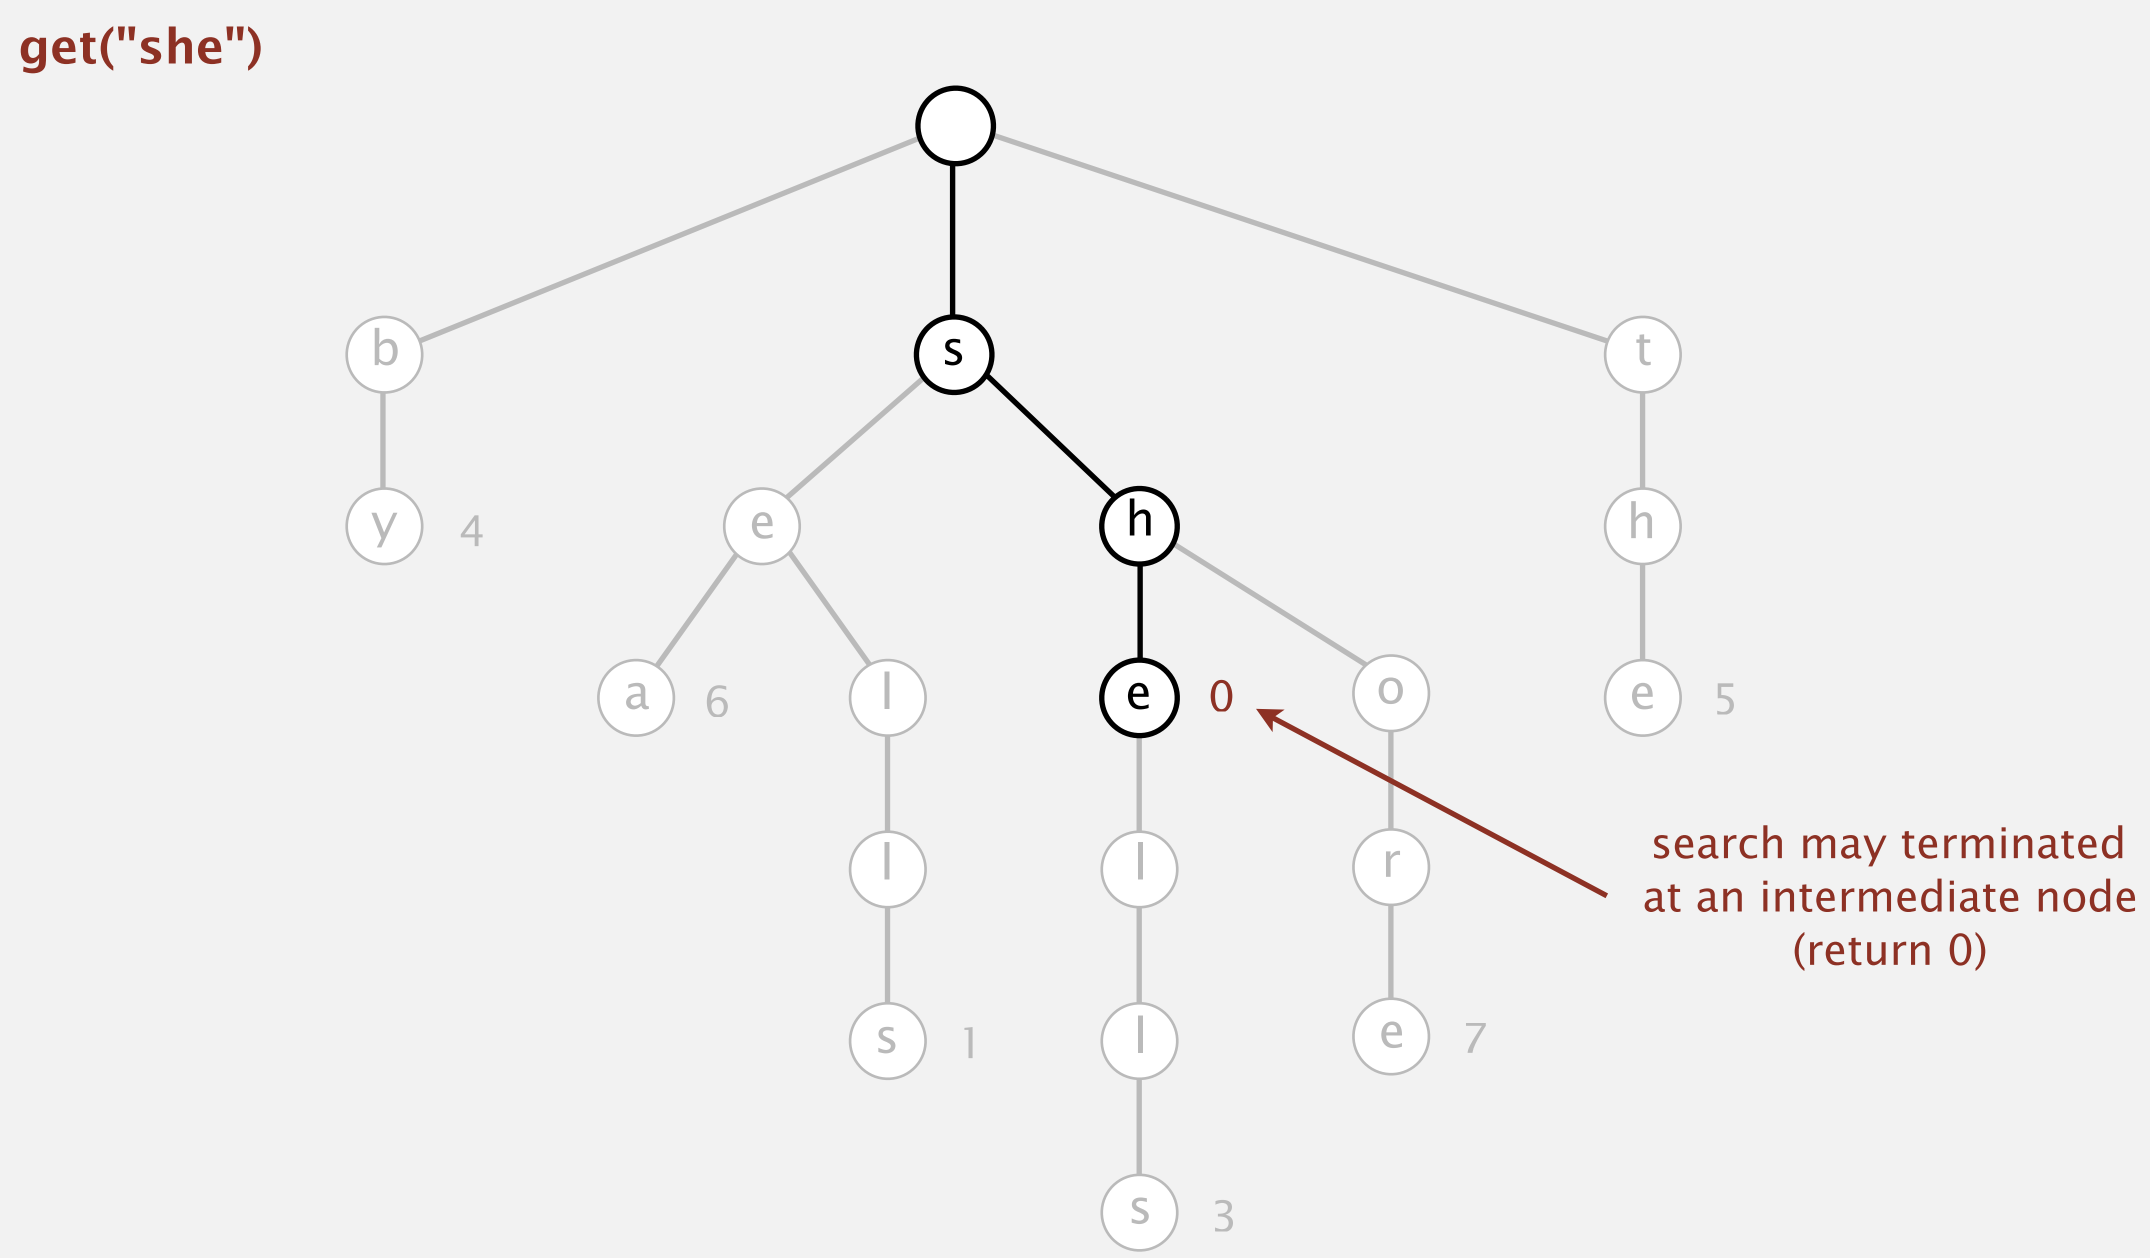
get("shells")



Search in a trie

Follow links corresponding to each character in the key.

- Search hit: node where search ends has a non-null value.
- Search miss: reach null link or node where search ends has null value.

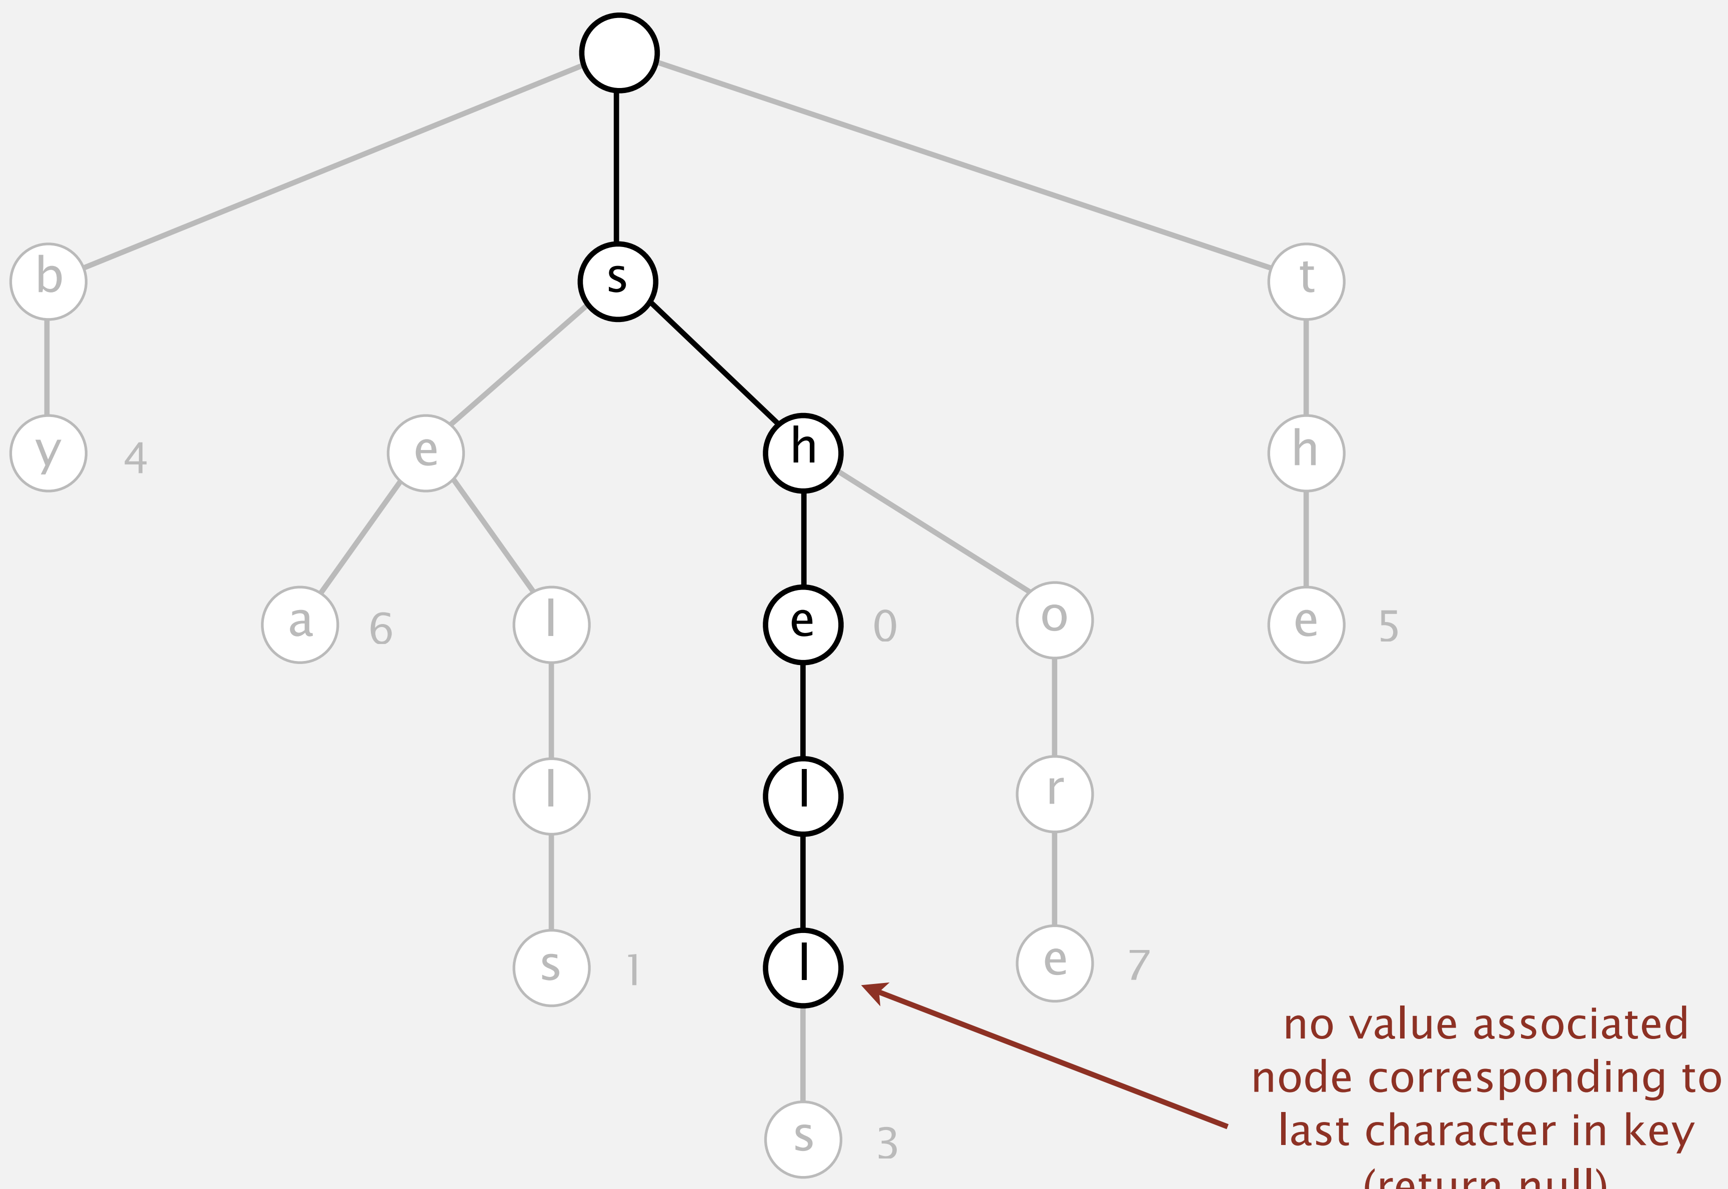


Search in a trie

Follow links corresponding to each character in the key.

- Search hit: node where search ends has a non-null value.
- Search miss: reach null link or node where search ends has null value.

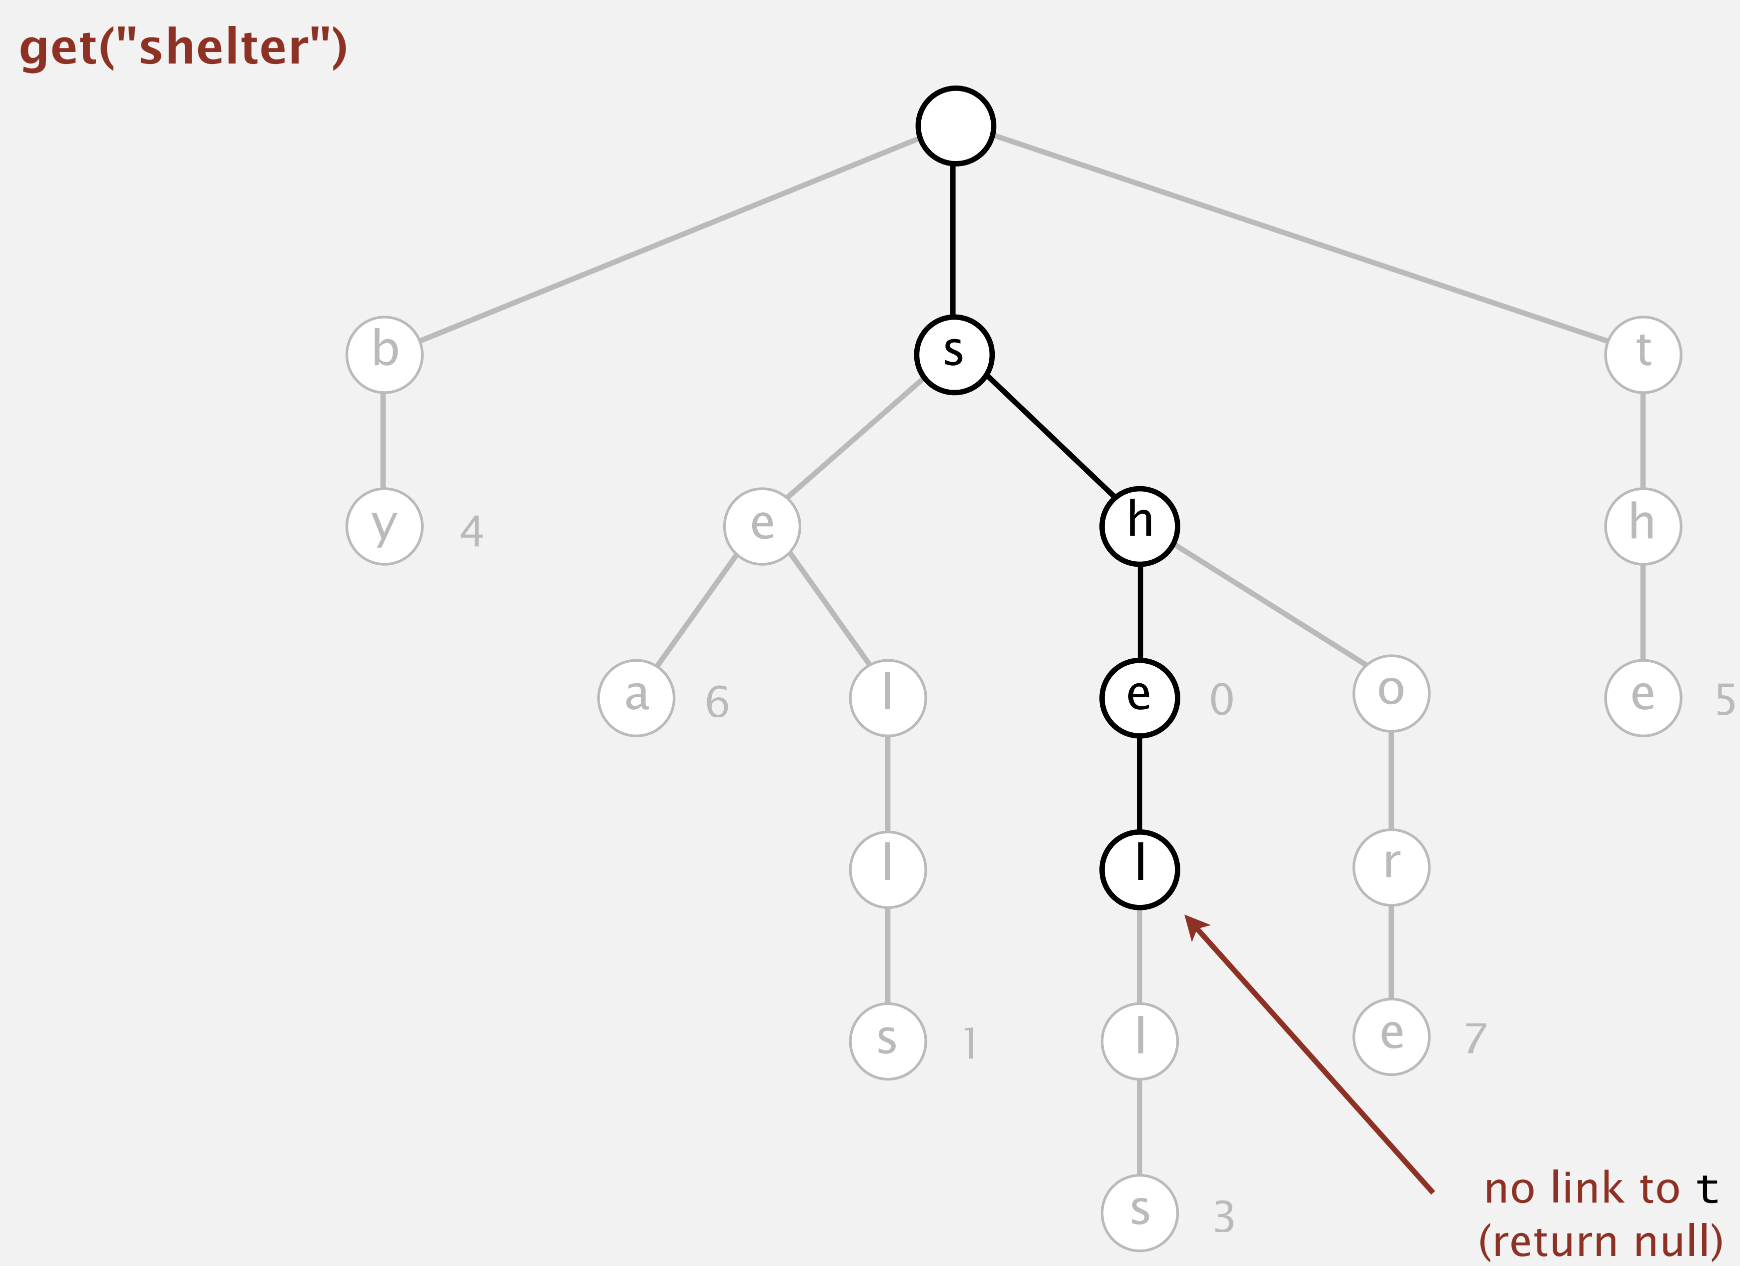
get("shell")



Search in a trie

Follow links corresponding to each character in the key.

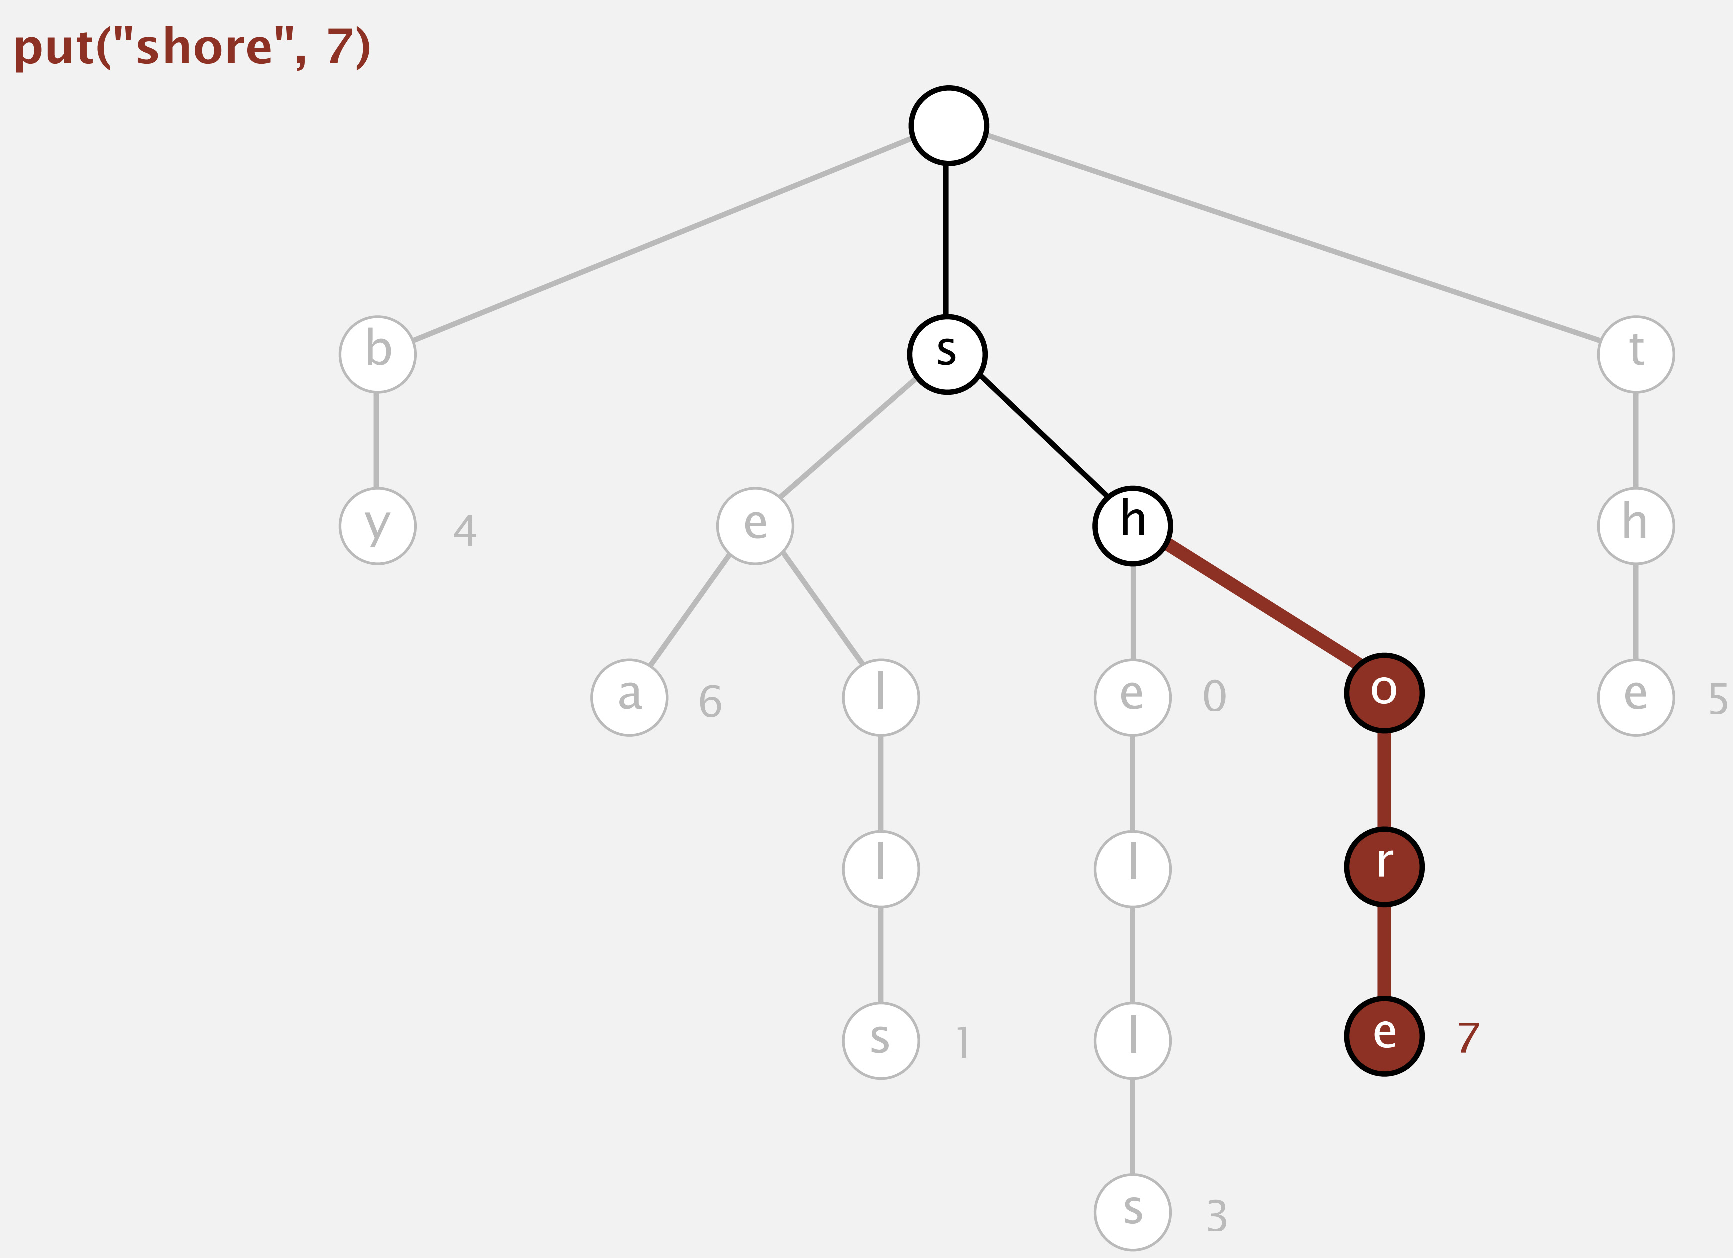
- Search hit: node where search ends has a non-null value.
- Search miss: reach null link or node where search ends has null value.



Insertion into a trie

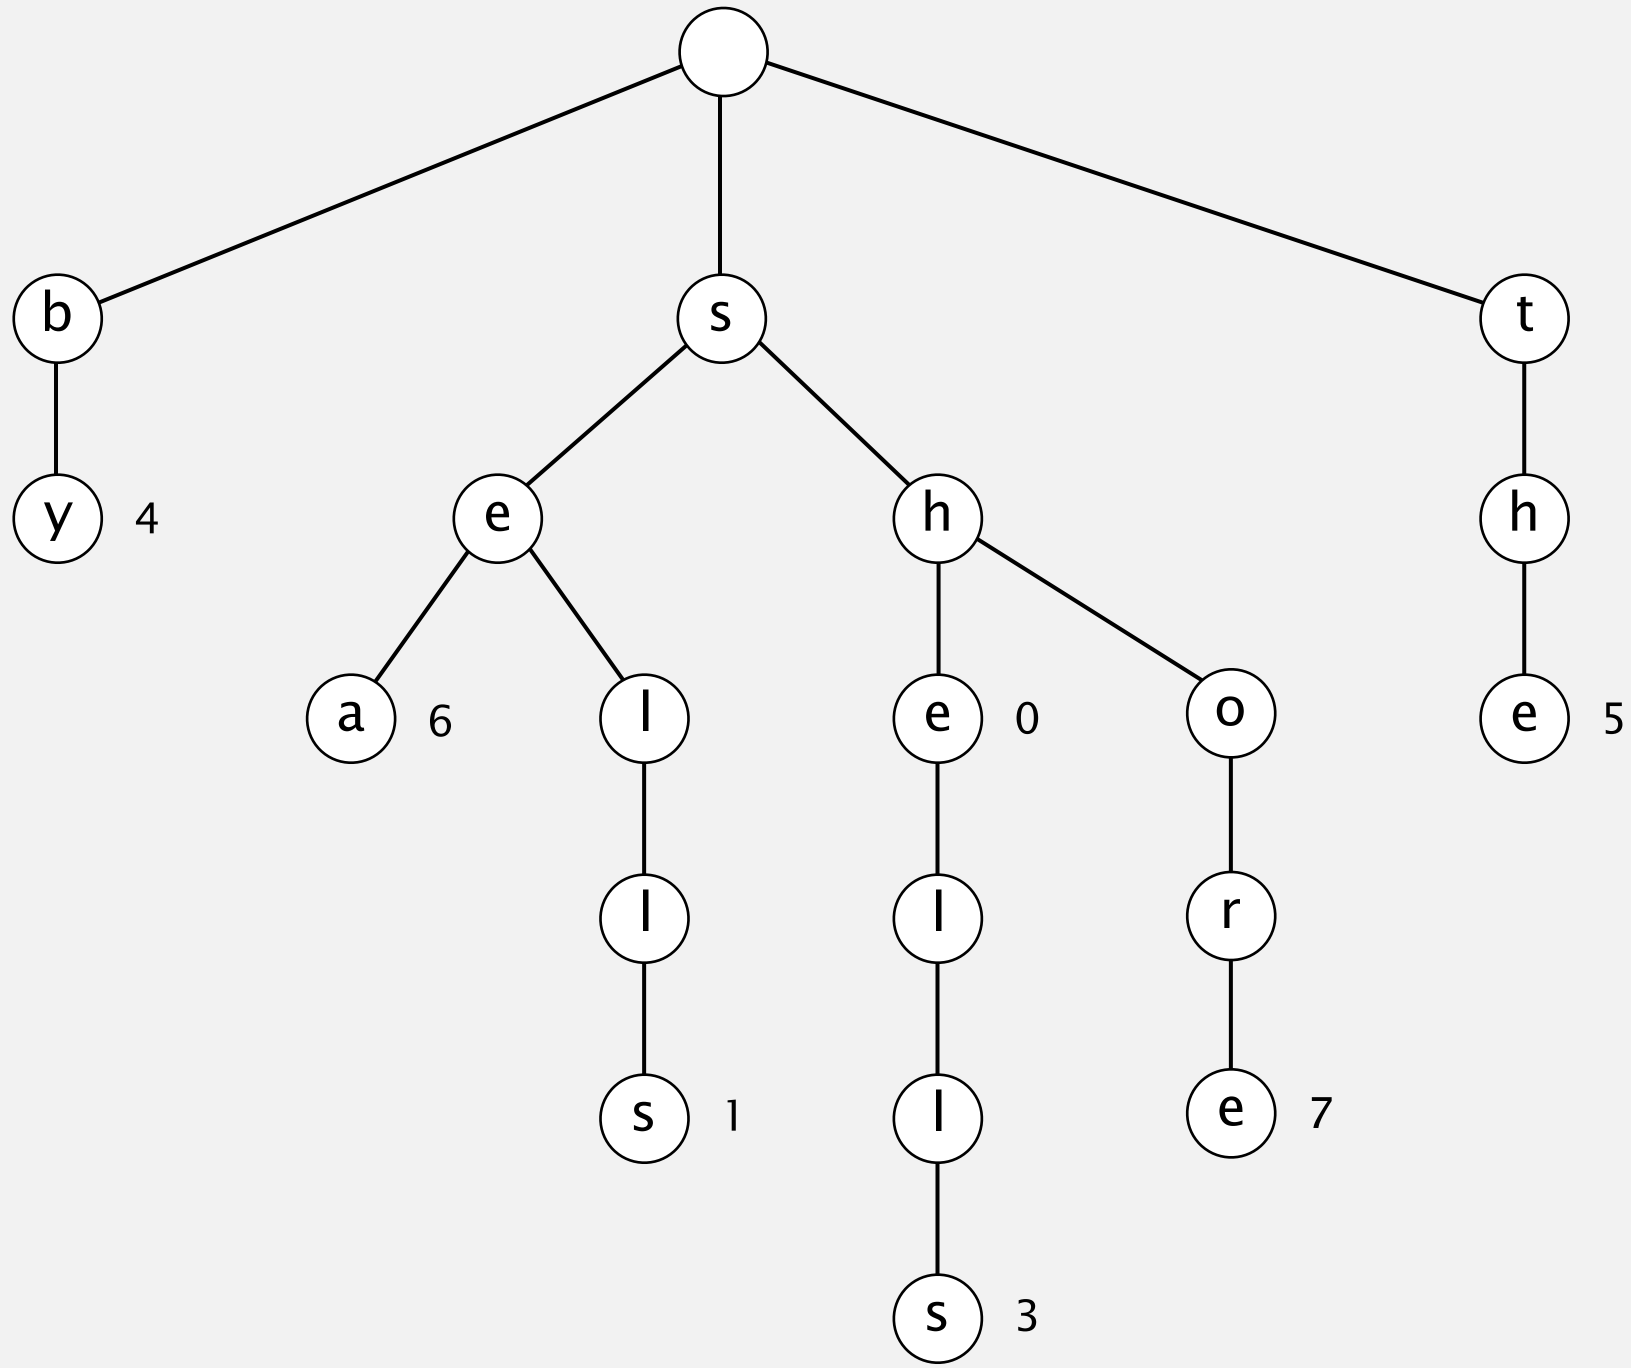
Follow links corresponding to each character in the key.

- Encounter a null link: create new node.
- Encounter the last character of the key: set value in that node.



Trie construction demo

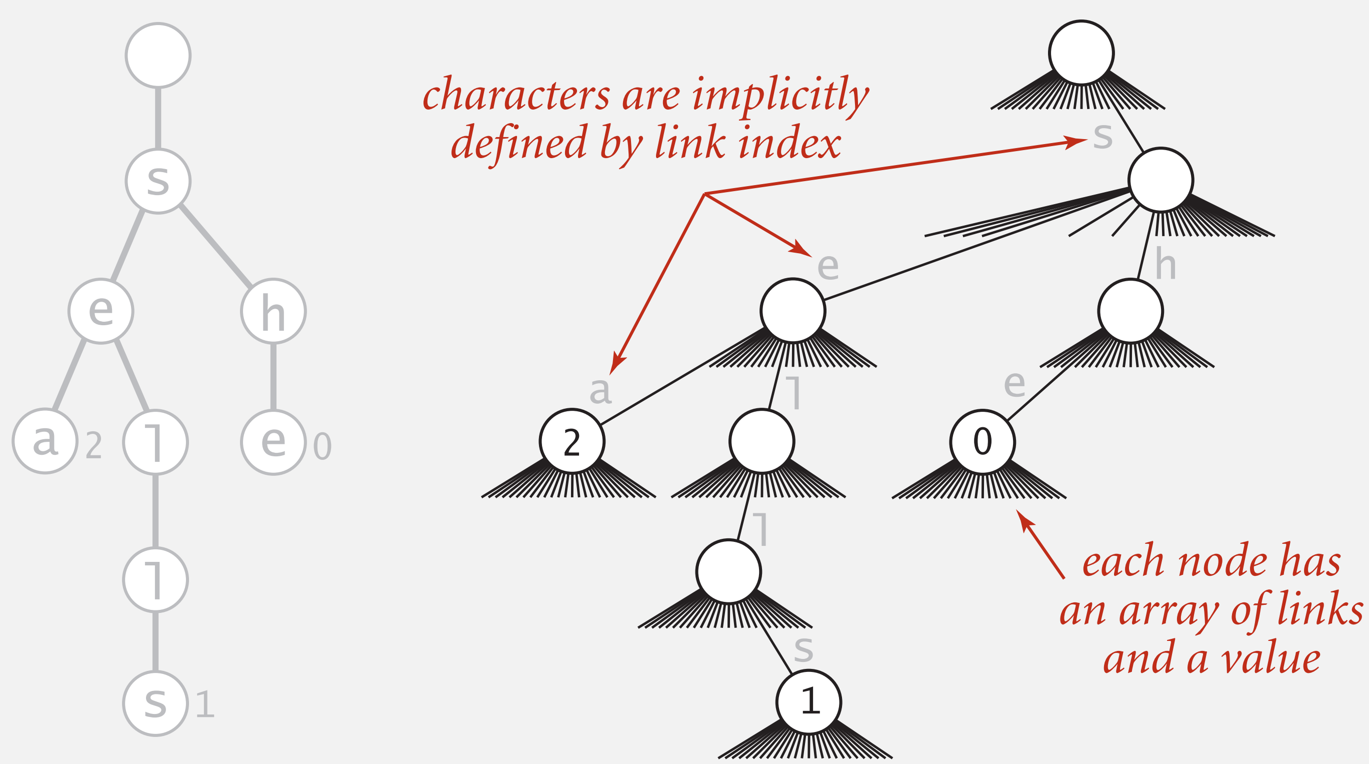
trie



Trie representation: Java implementation

Node. A value, plus references to R nodes.

```
private static class Node
{
   private Object val;  // no generic array creation
   private Node[] next = new Node[R];
}
```



Remark. Neither keys nor characters are stored explicitly.

R-way trie: Java implementation

```
public class TrieST<Value>
{
   private static final int R = 256;        ← extended ASCII
   private Node root = new Node();

   private static class Node
   {  /* see previous slide */  }

  public void put(String key, Value val)
  {  root = put(root, key, val, 0);  }

  private Node put(Node x, String key, Value val, int d)
  {
    if (x == null) x = new Node();
    if (d == key.length()) { x.val = val; return x; }
    char c = key.charAt(d);
    x.next[c] = put(x.next[c], key, val, d+1);
    return x;
 }
```

R-way trie: Java implementation (continued)

```
...

    public Value get(String key)
    {  return get(root, key, 0);  }

    private Value get(Node x, String key, int d)
    {
       if (x == null) return null;
       if (d == key.length())
          return (Value) x.val;   // cast needed
       char c = key.charAt(d);
       return get(x.next[c], key, d+1);
    }

}
```

Trie quiz 1

What is order of growth of the running time (in the worst case) to insert a key of length L into an R–way trie?

- **A.** L
- **B.** $R + L$
- **C.** $n + L$
- **D.** $R\,L$

R = alphabet size

L = length of key

n = number of keys

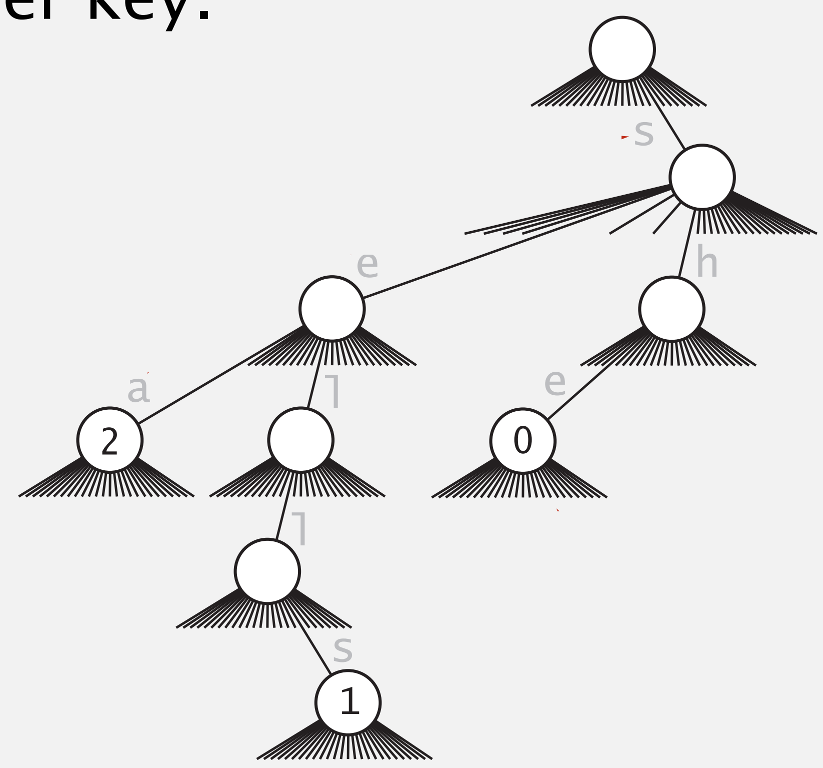
Trie performance

Search hit. Need to examine all L characters for equality.

Search miss.

- Worst case: examine L characters.
- Typical case: examine only a few characters before mismatch (sublinear).

Space. At least R links per key.



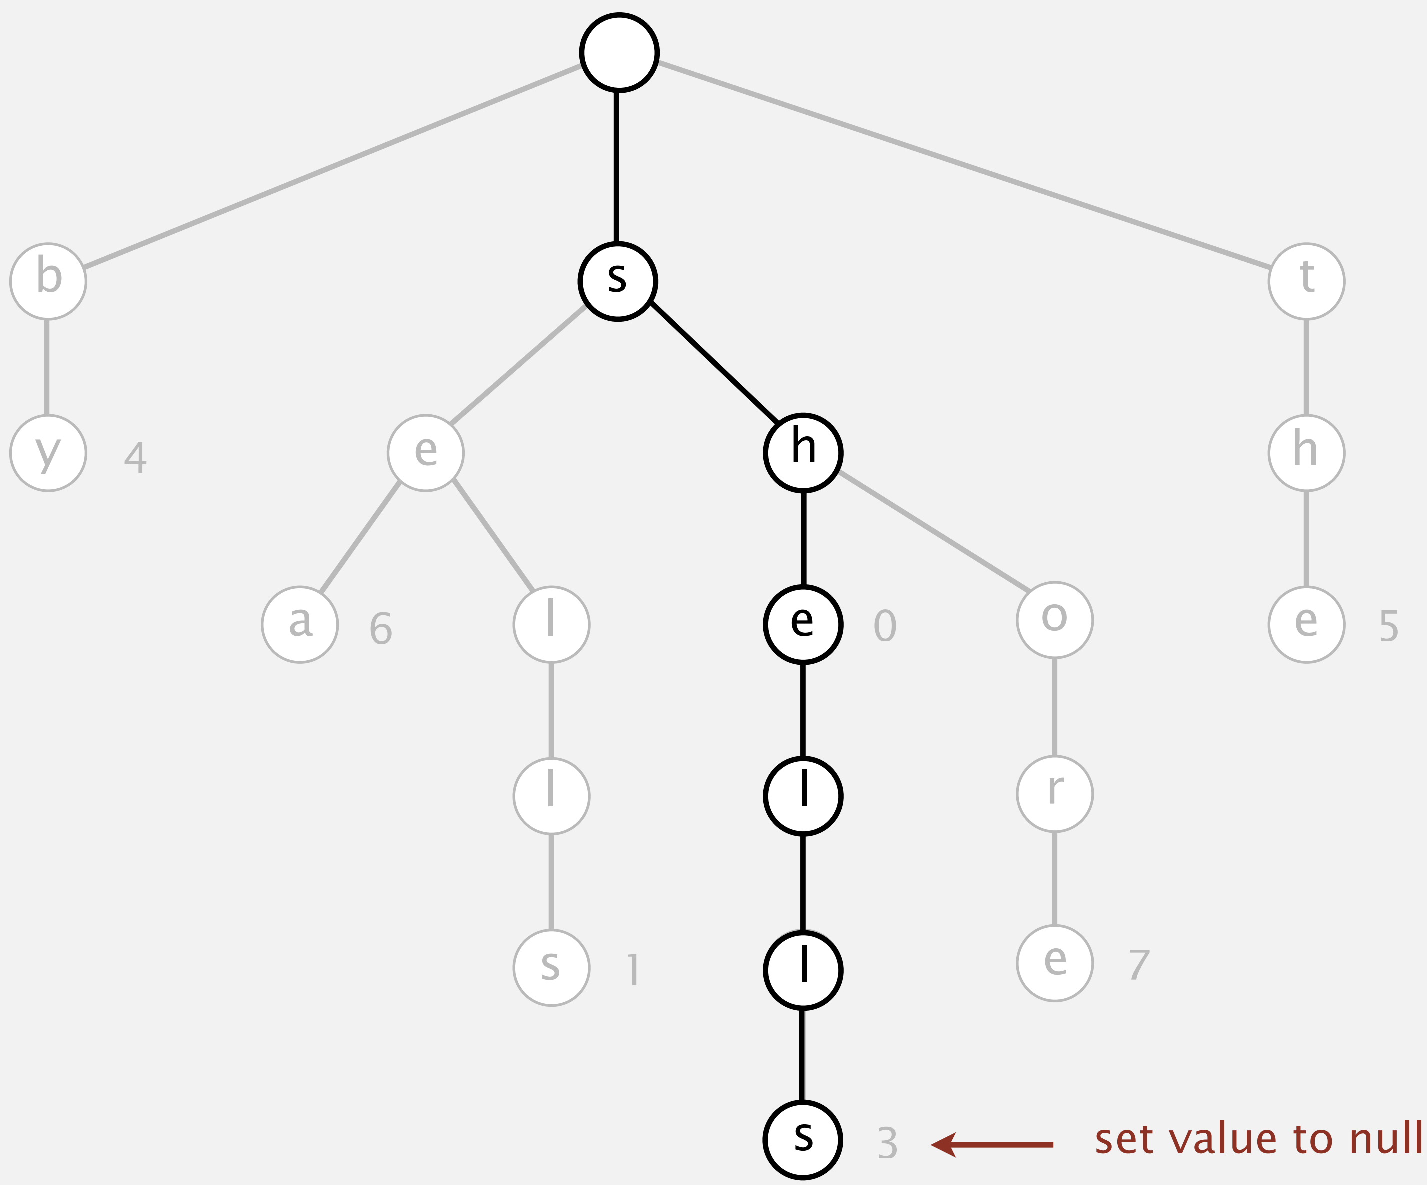
Bottom line. Fast search hit and even faster search miss, but wastes space.

Deletion in an R-way trie

To delete a key–value pair:

- Find the node corresponding to key and set value to null.
- If node has null value and all null links, remove that node (and recur).

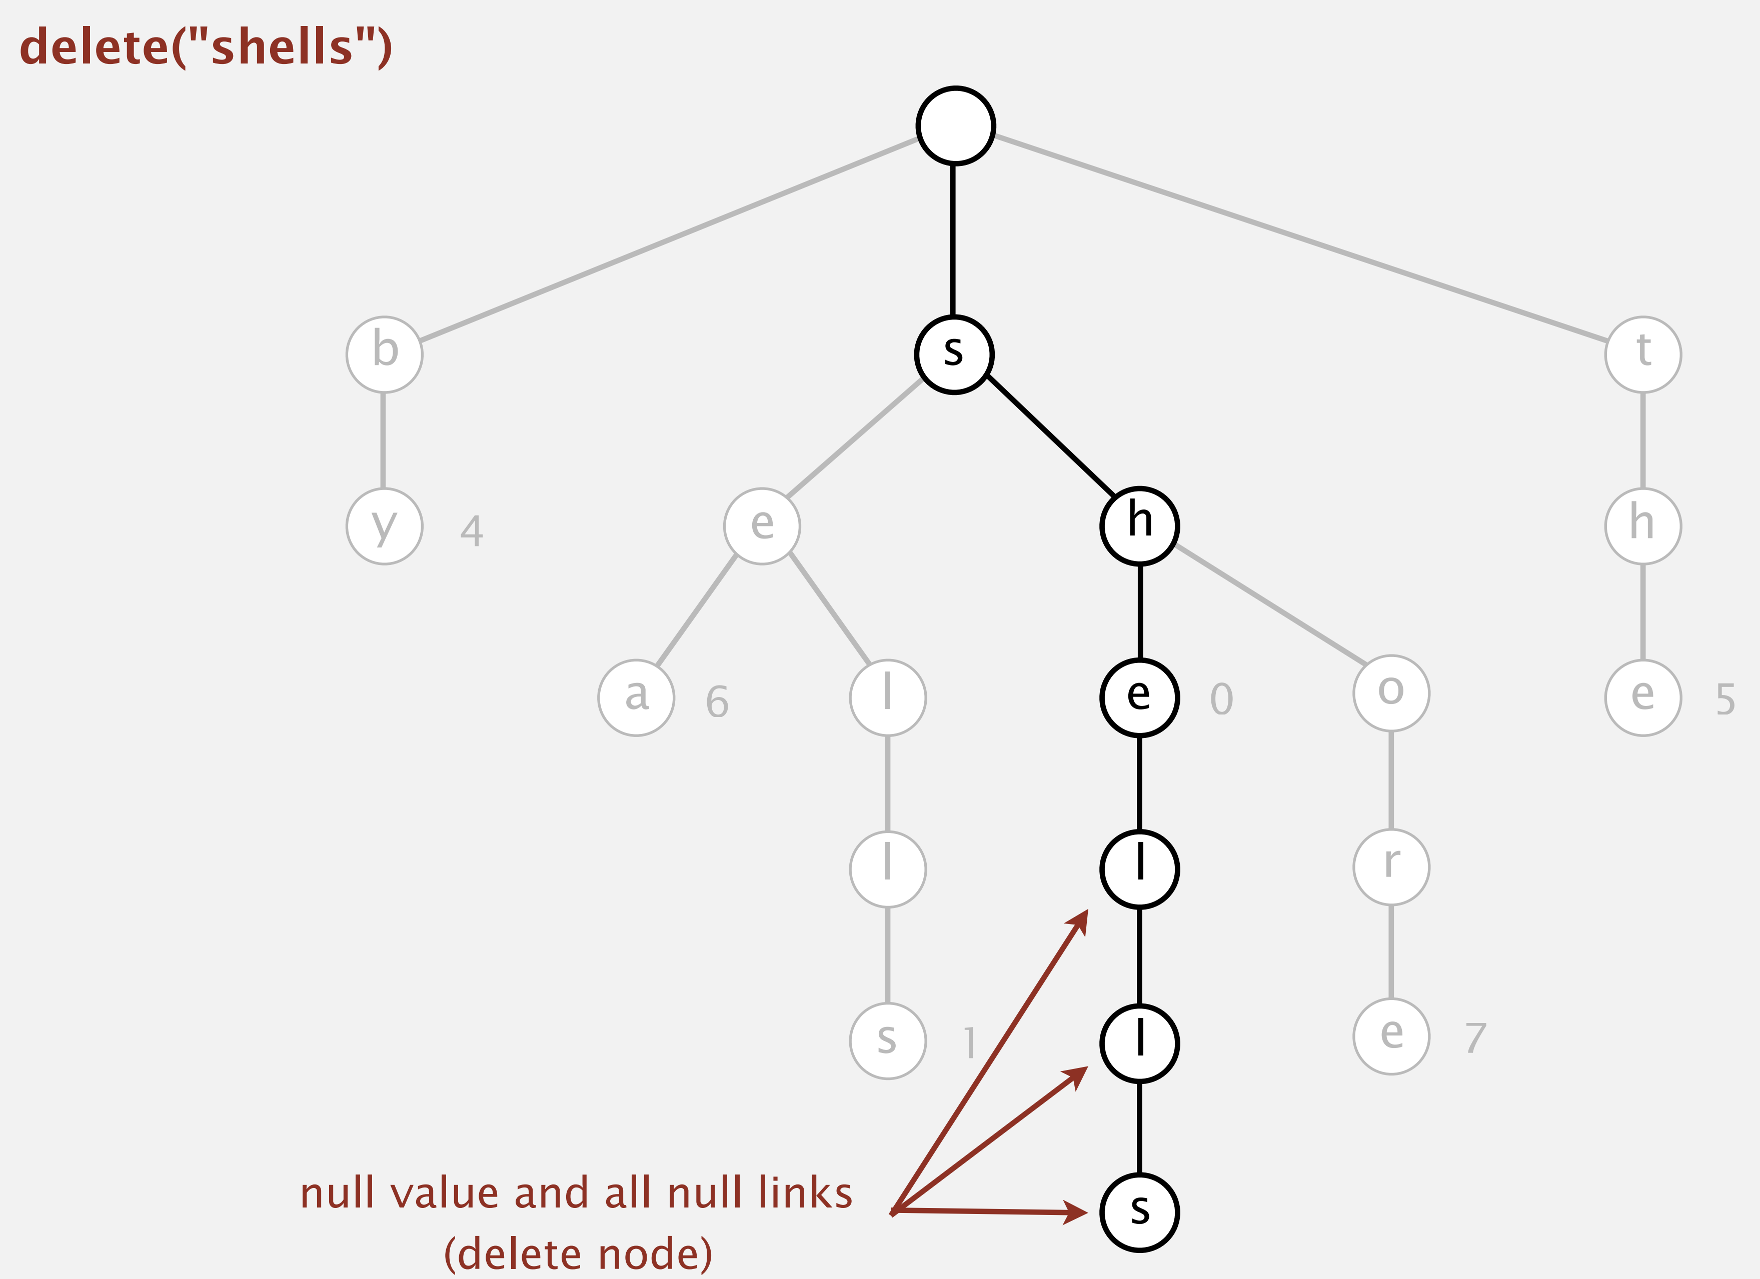
delete("shells")



Deletion in an R-way trie

To delete a key–value pair:

- Find the node corresponding to key and set value to null.
- If node has null value and all null links, remove that node (and recur).



String symbol table implementations cost summary

	character accesses (typical case)				dedup	
implementation	**search hit**	**search miss**	**insert**	**space (references)**	**moby.txt**	**actors.txt**
red-black BST	$L + c \lg^2 n$	$c \lg^2 n$	$c \lg^2 n$	$4n$	1.4	97.4
hashing (linear probing)	L	L	L	$4n$ to $16n$	0.76	40.6
R-way trie	L	$\log_R n$	$R + L$	$(R+1)\, n$	1.12	*out of memory*

R-way trie.

- Method of choice for small R.
- Works well for medium R.
- Too much memory for large R.

Challenge. Use less memory, e.g., a 65,536-way trie for Unicode!

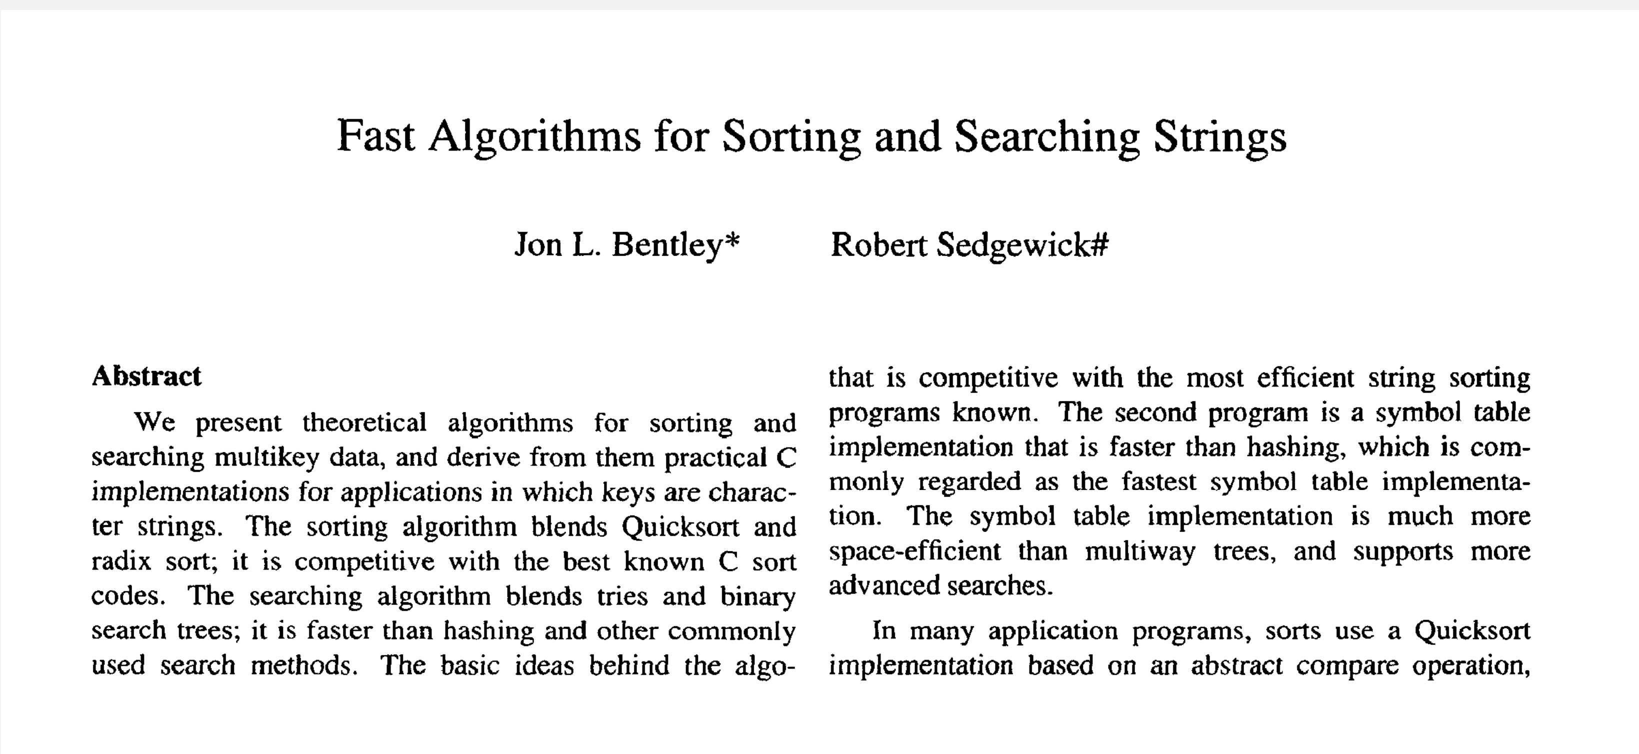
https://algs4.cs.princeton.edu

5.2 Tries

- *R-way tries*
- *ternary search tries*
- *character-based operations*

Ternary search tries

- Store characters and values in nodes (not keys).
- Each node has 3 children: smaller (left), equal (middle), larger (right).



Fast Algorithms for Sorting and Searching Strings

Jon L. Bentley* Robert Sedgewick#

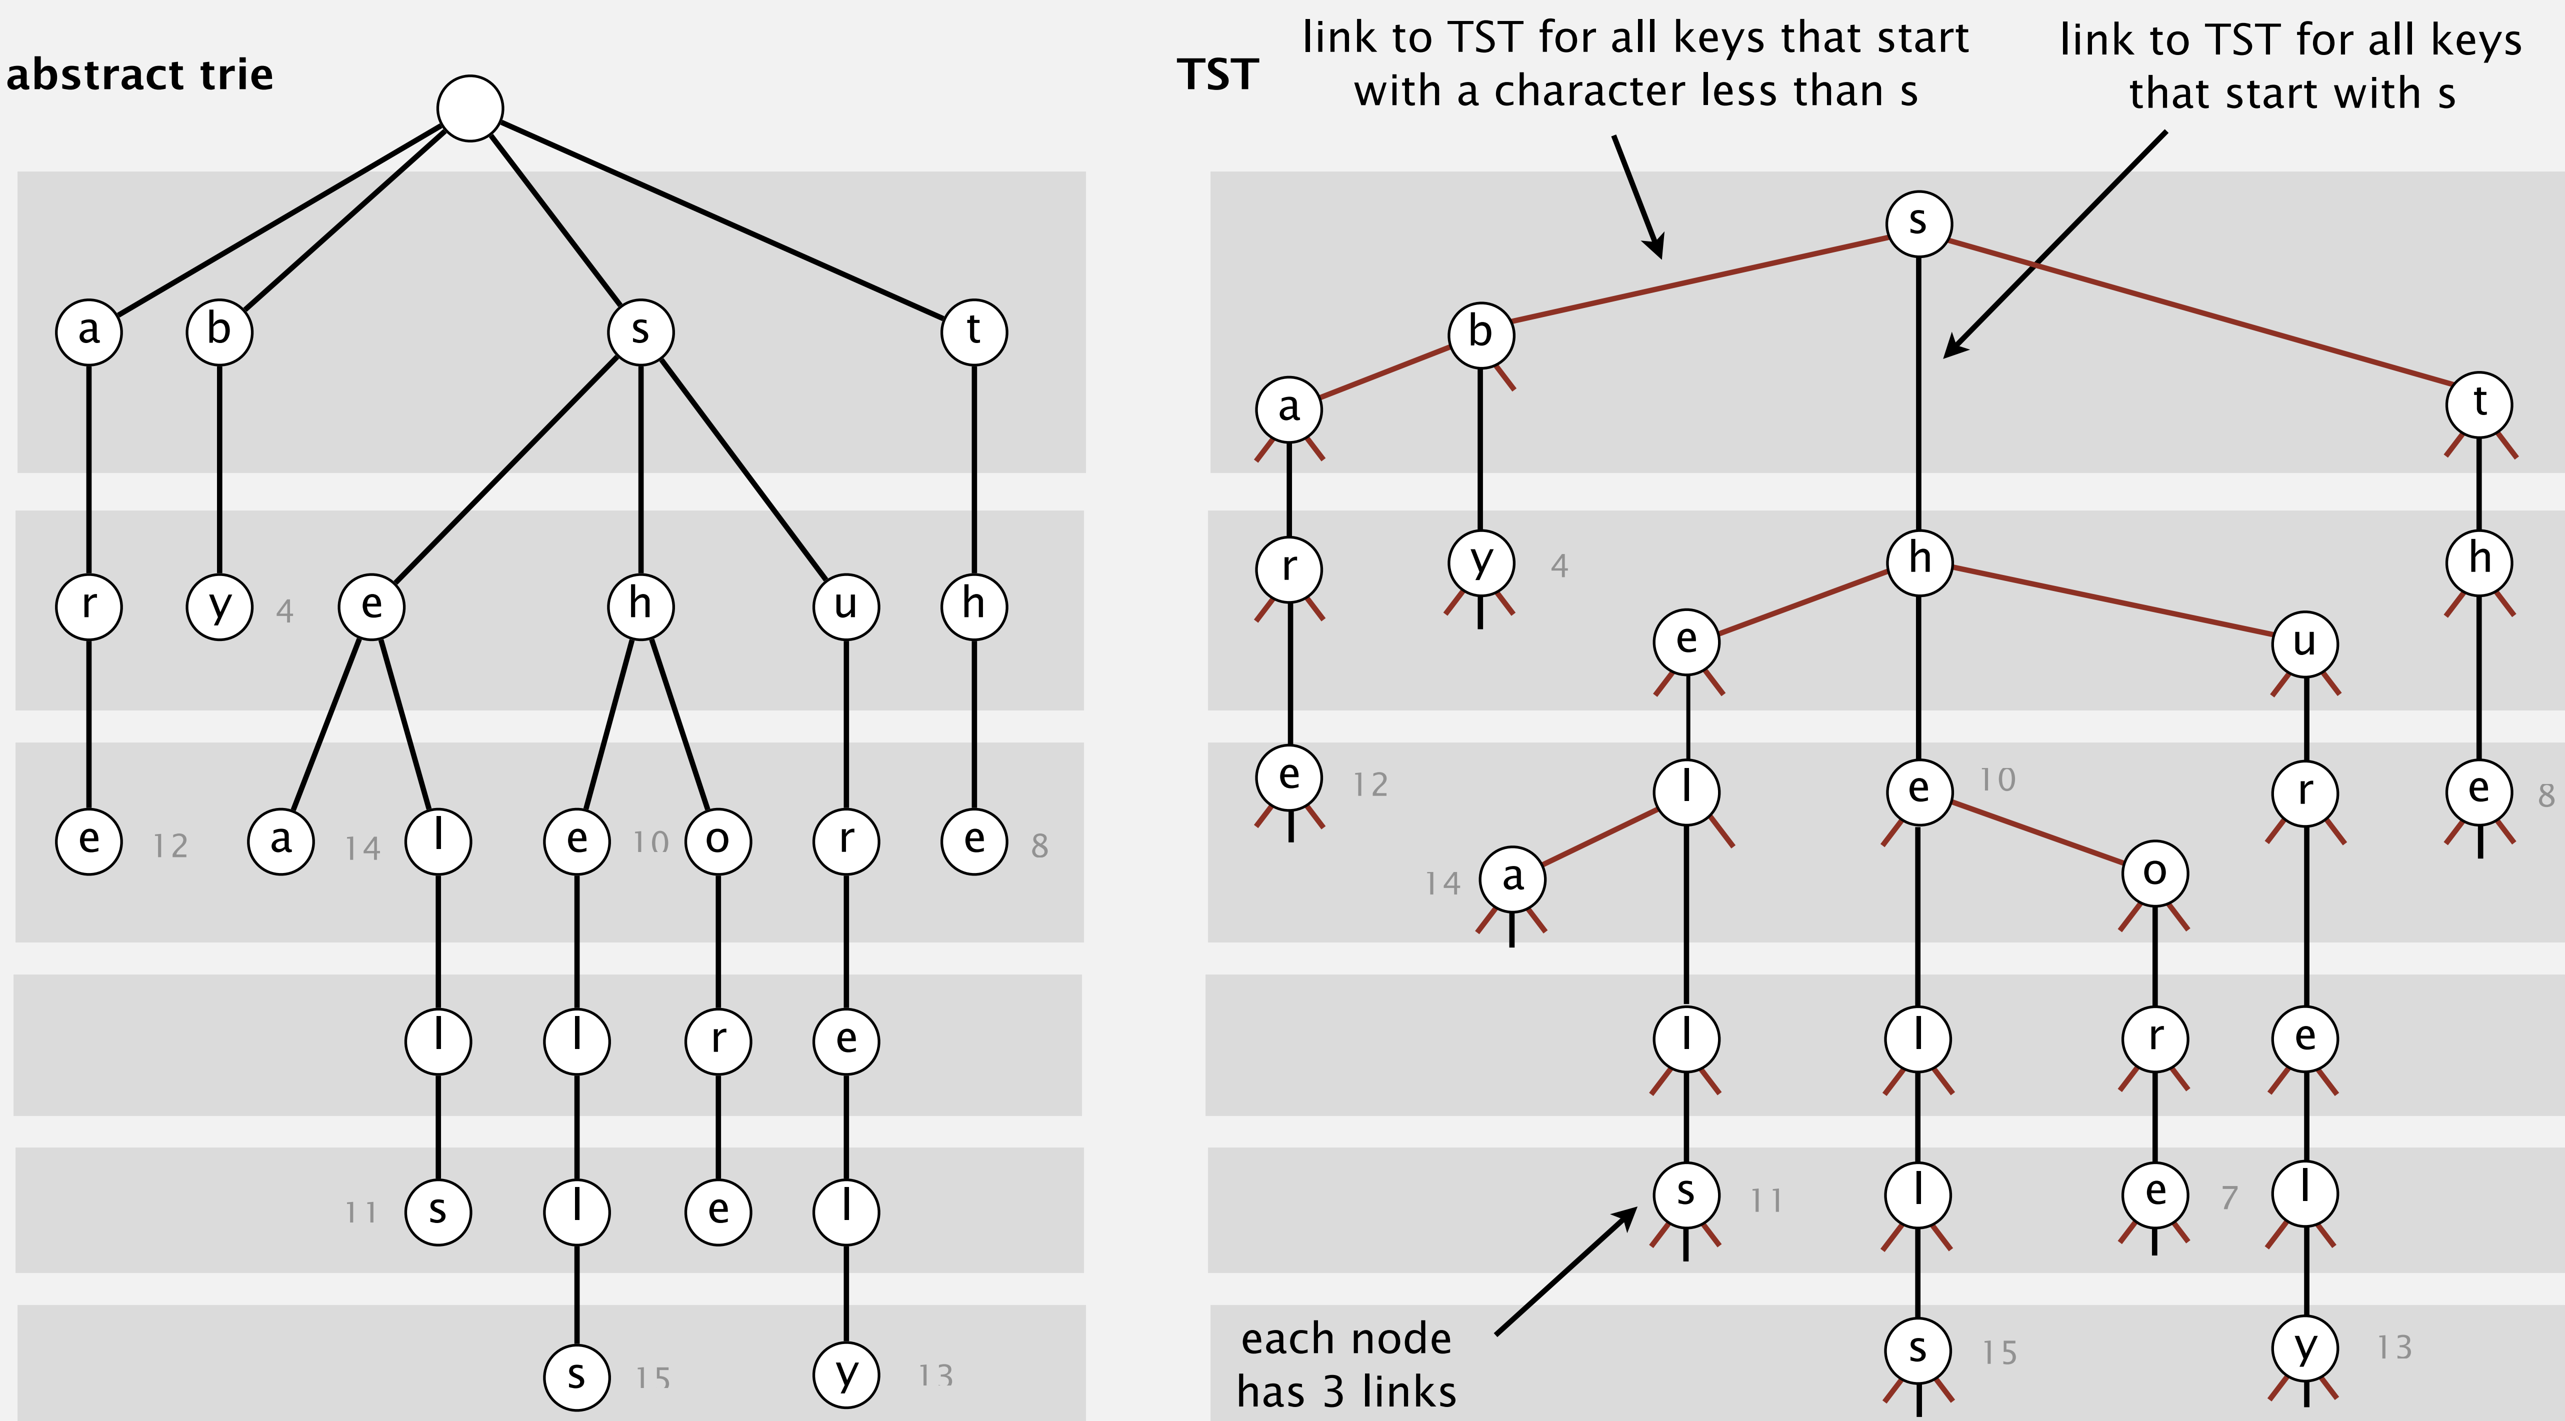
Abstract

We present theoretical algorithms for sorting and searching multikey data, and derive from them practical C implementations for applications in which keys are character strings. The sorting algorithm blends Quicksort and radix sort; it is competitive with the best known C sort codes. The searching algorithm blends tries and binary search trees; it is faster than hashing and other commonly used search methods. The basic ideas behind the algo- that is competitive with the most efficient string sorting programs known. The second program is a symbol table implementation that is faster than hashing, which is commonly regarded as the fastest symbol table implementation. The symbol table implementation is much more space-efficient than multiway trees, and supports more advanced searches.

In many application programs, sorts use a Quicksort implementation based on an abstract compare operation,

Ternary search tries

- Store characters and values in nodes (not keys).
- Each node has 3 children: smaller (left), equal (middle), larger (right).



Trie quiz 2

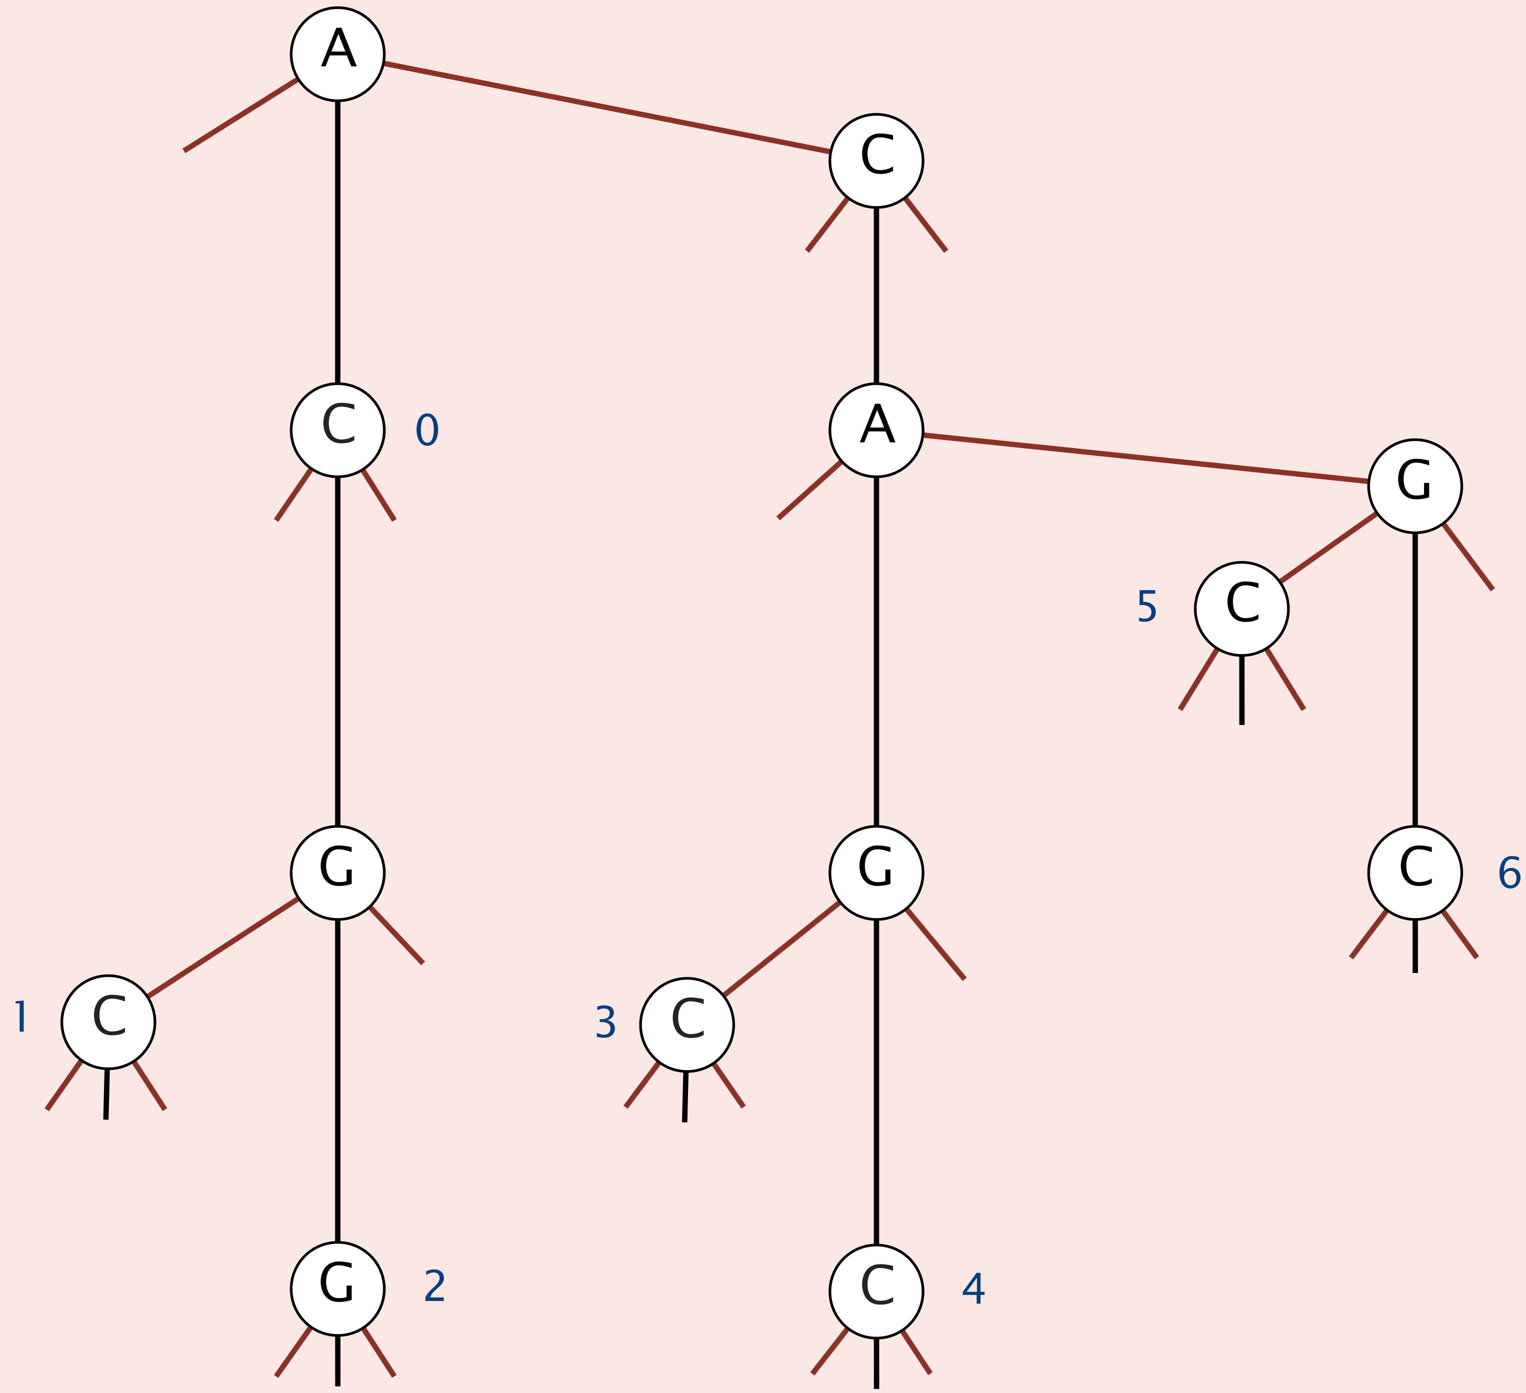
Which value is associated with the key CAC ?

A. 3

B. 4

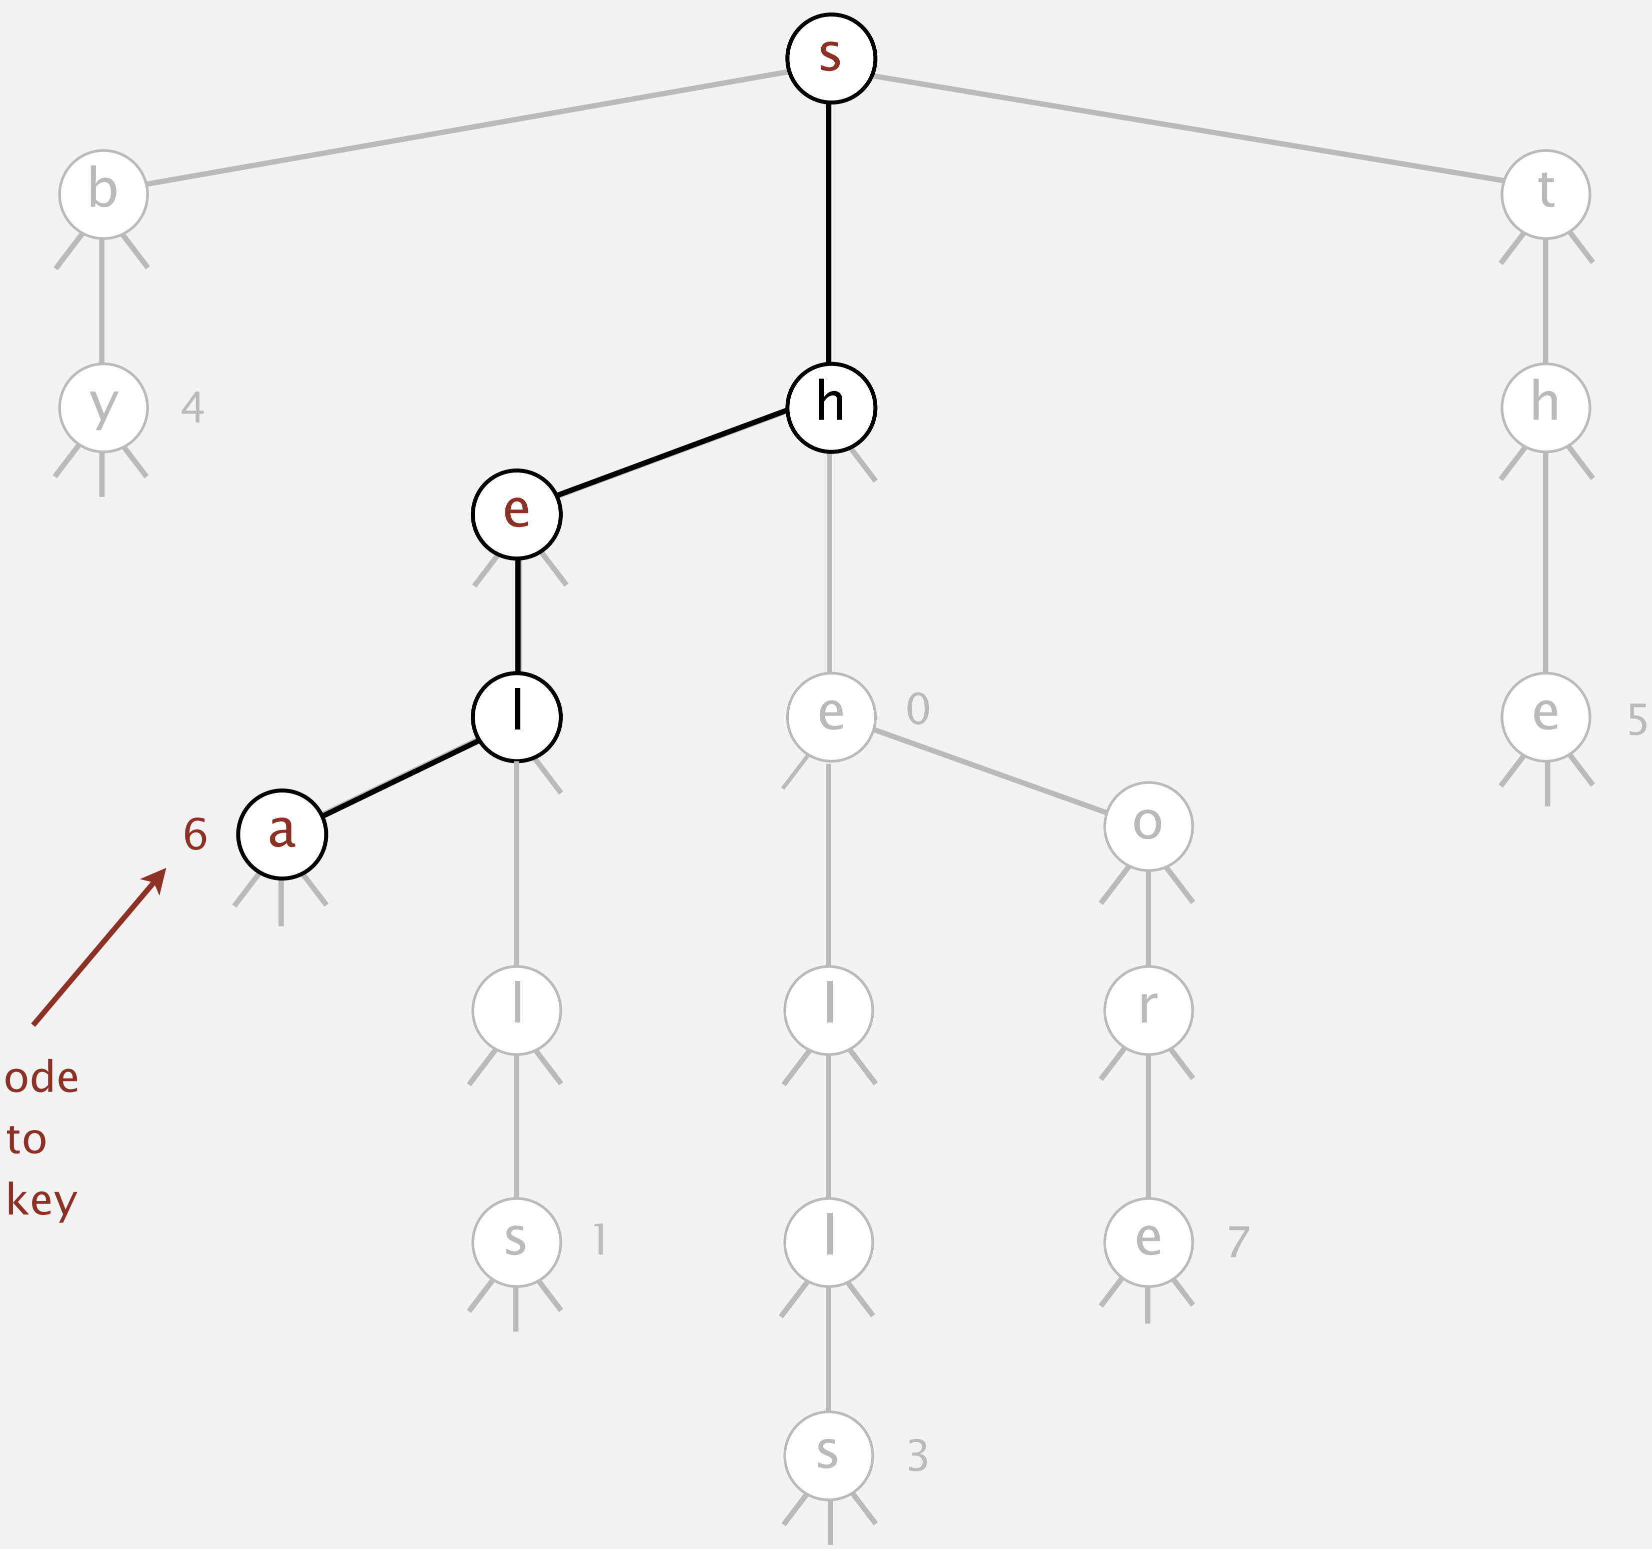
C. 5

D. *null*



Search hit in a TST

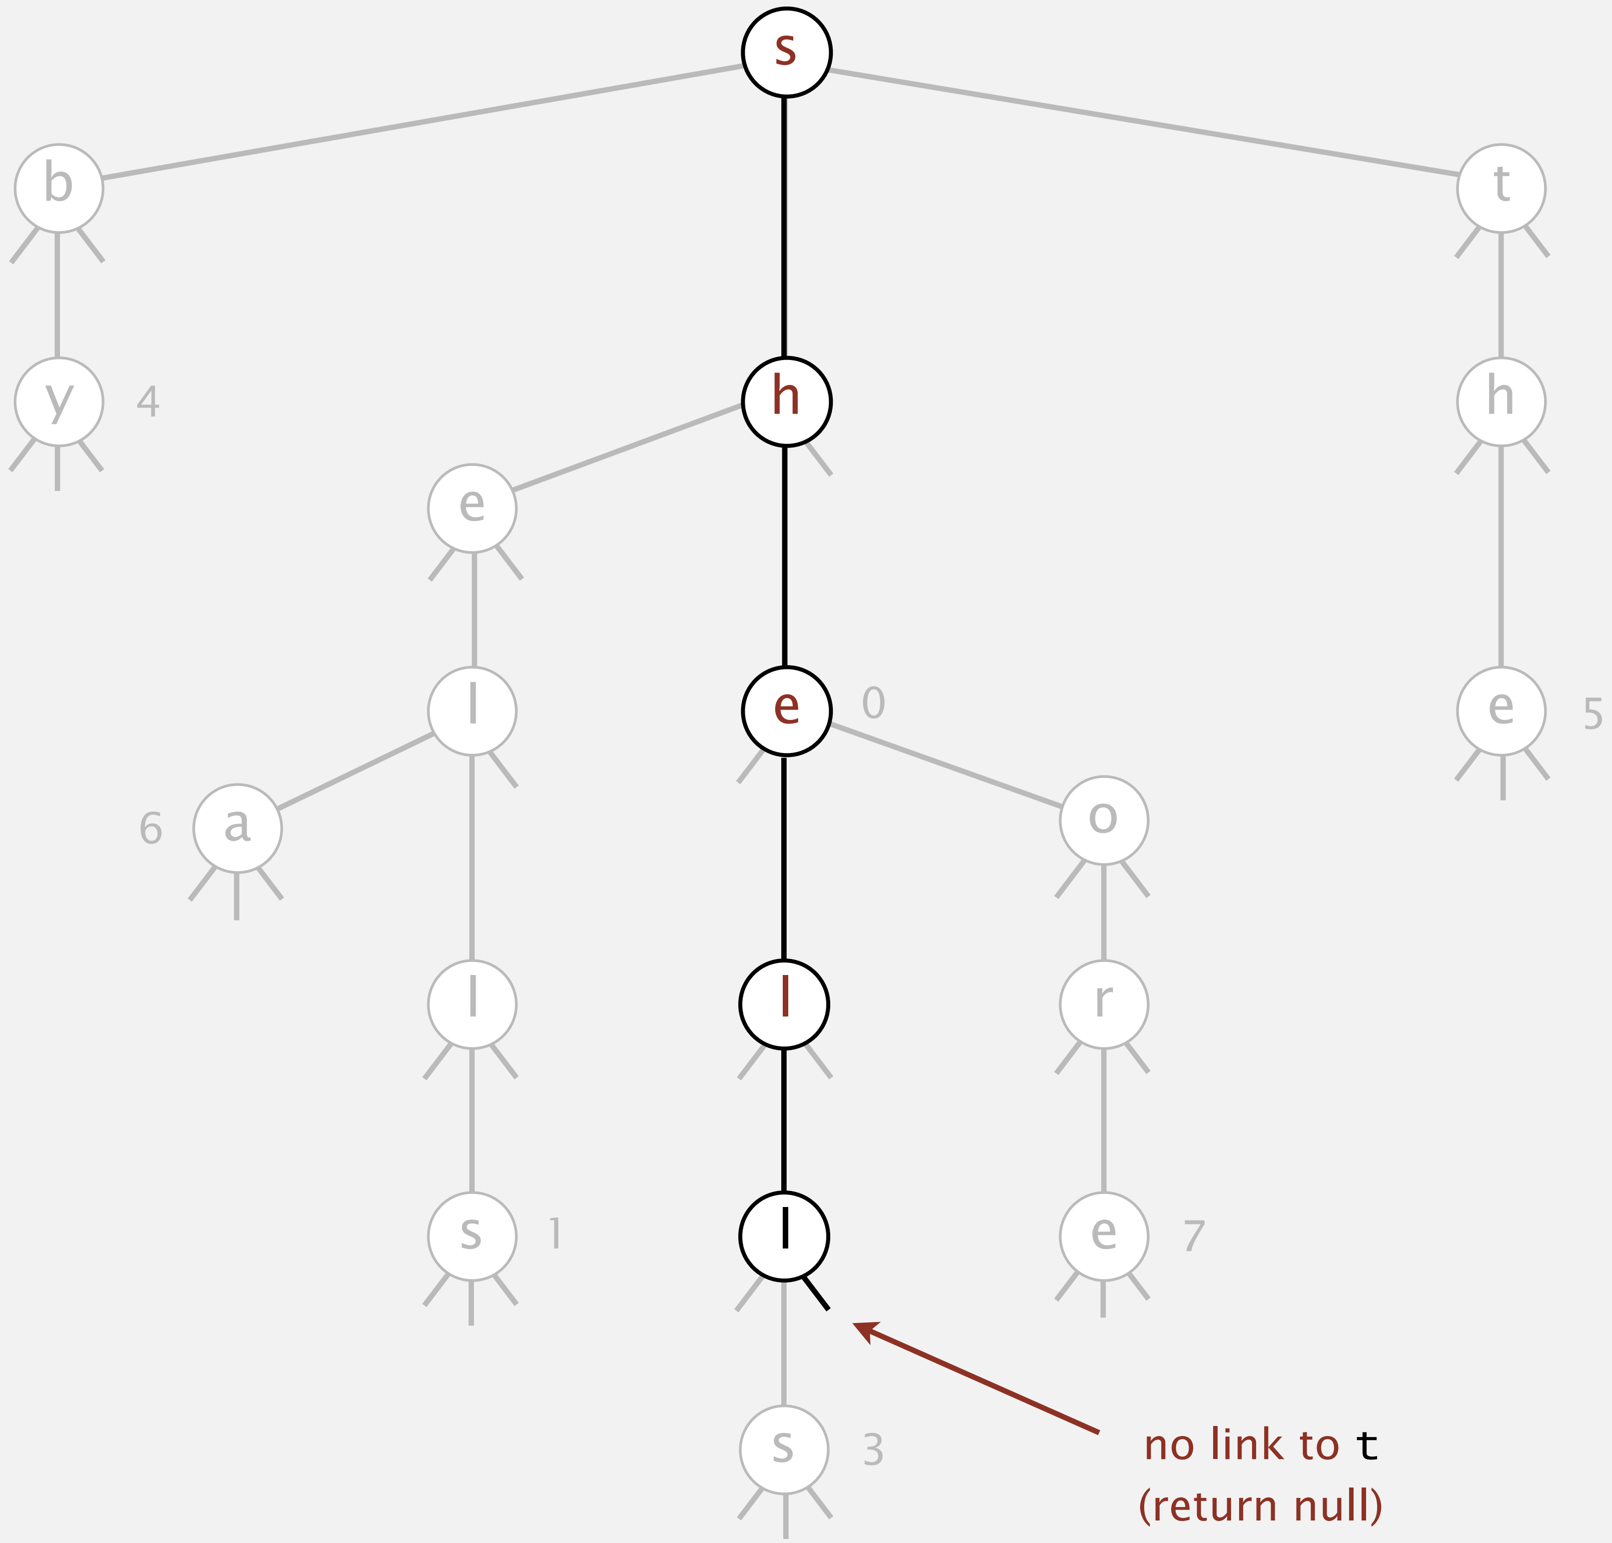
get("sea")



return value in node
corresponding to
last character in key

Search miss in a TST

get("shelter")



Search in a TST

Follow links corresponding to each character in the key.

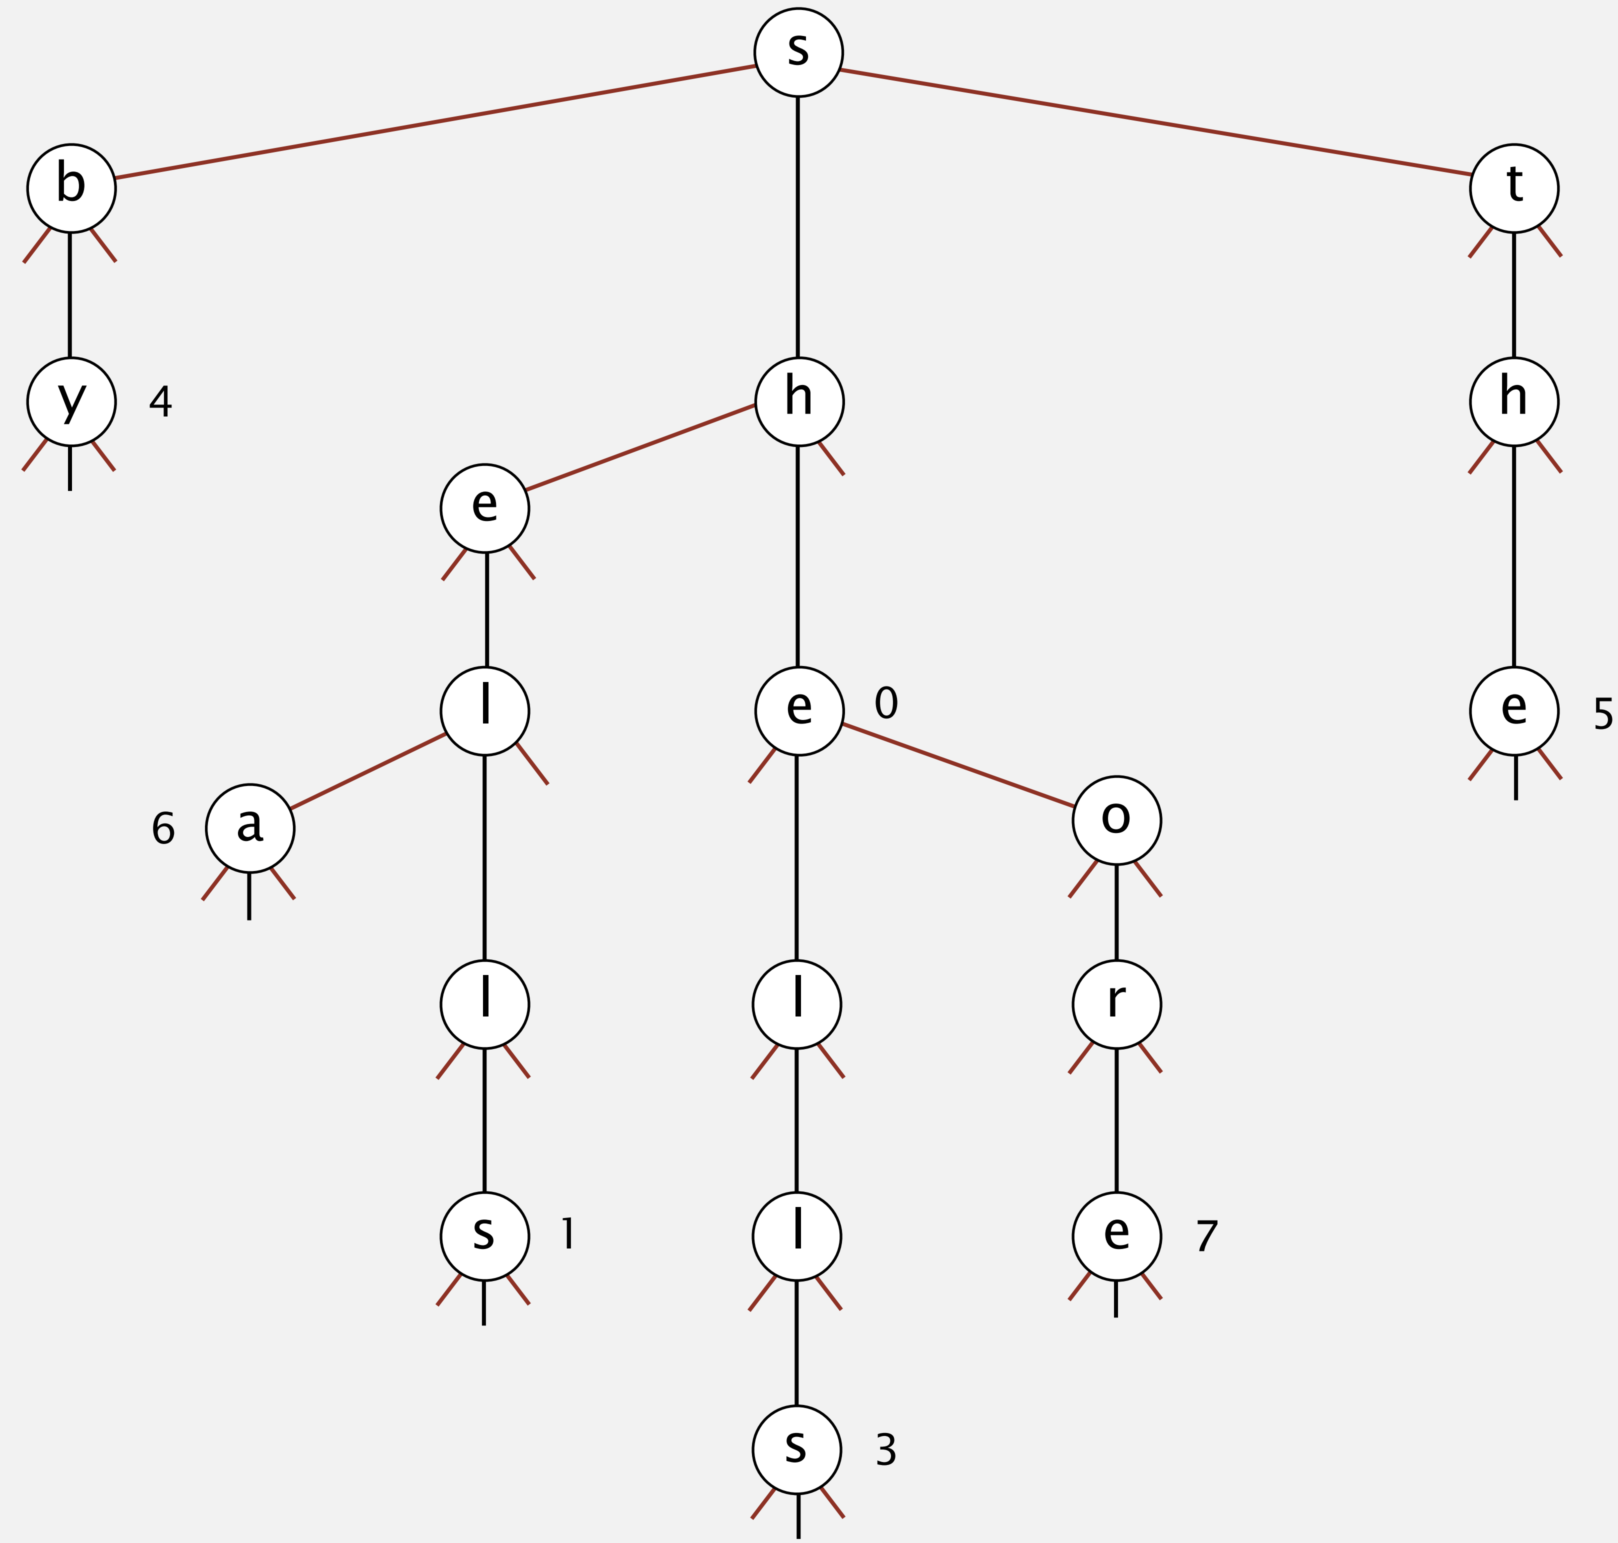
- If less, take left link; if greater, take right link.
- If equal, take the middle link and move to the next key character.

Search hit. Node where search ends has a non-null value.

Search miss. Reach a null link or node where search ends has null value.

Ternary search trie construction demo

ternary search trie



Trie quiz 3

In which subtrie would the key CCC be inserted?

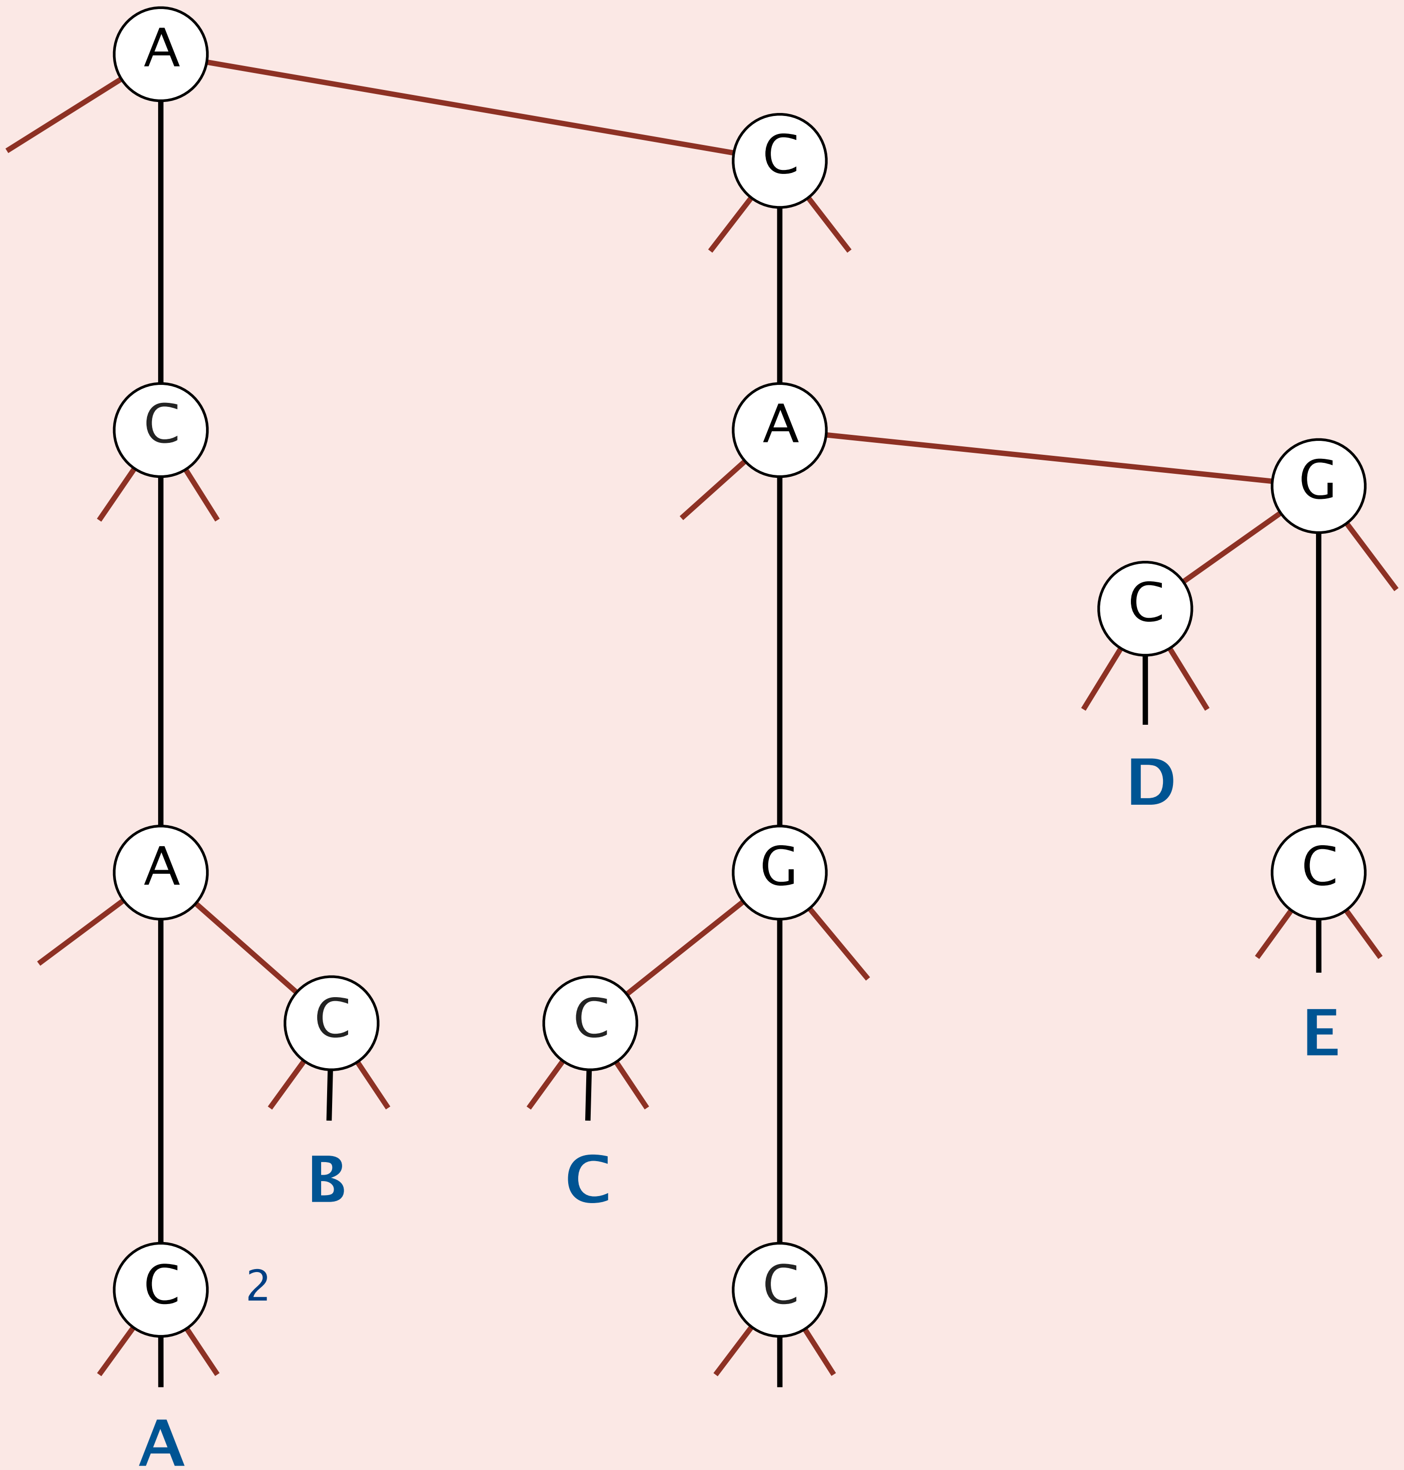
A.

B.

C.

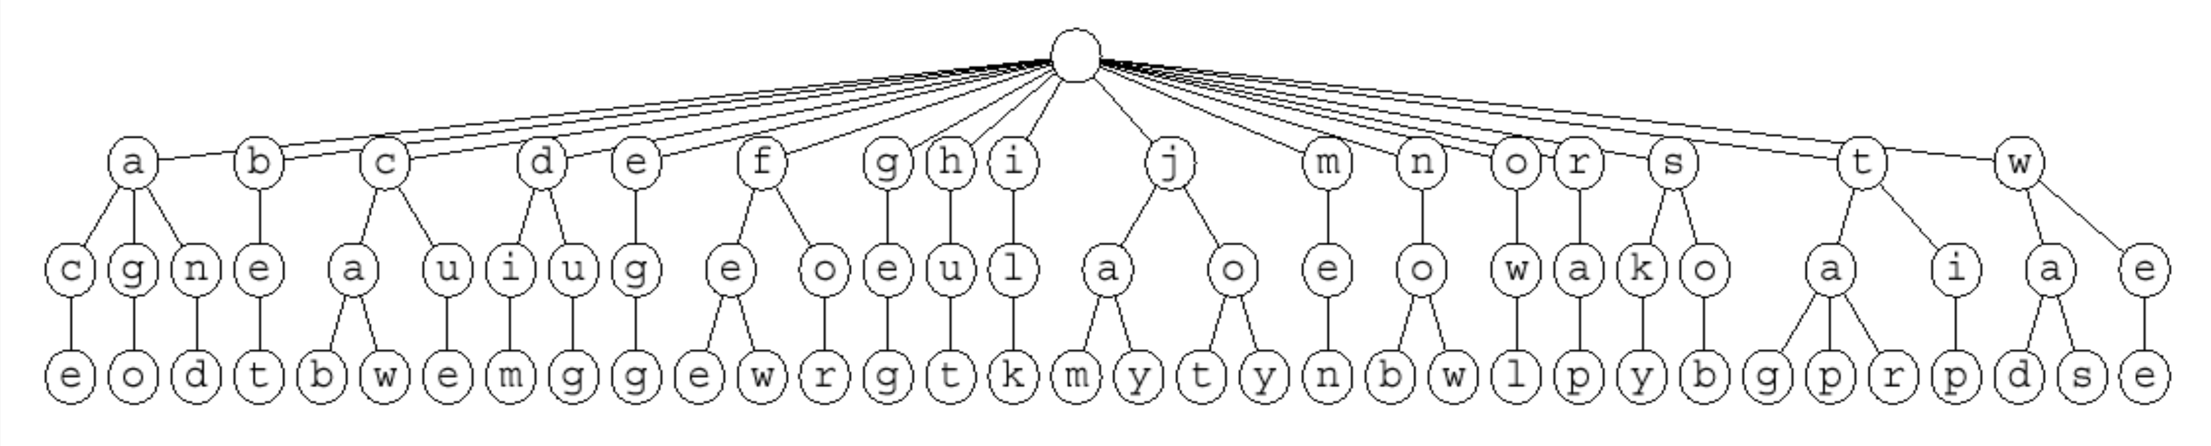
D.

E.



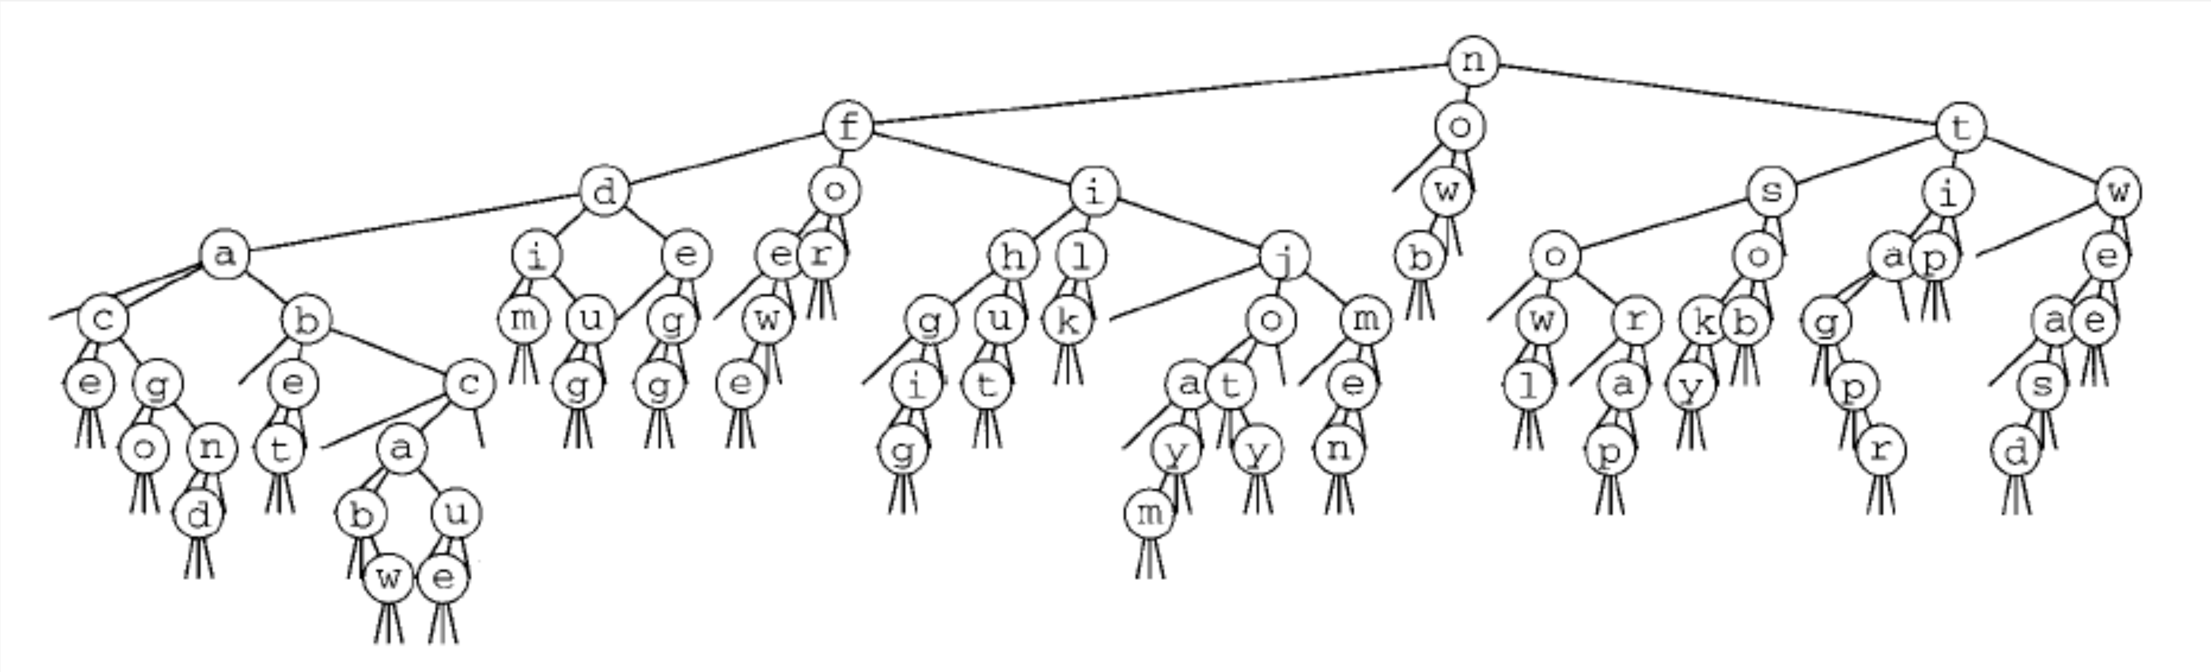
26-way trie vs. TST

26-way trie. 26 null links in each leaf.



26-way trie (1035 null links, not shown)

TST. 3 null links in each leaf.



TST (155 null links)

```
now
for
tip
ilk
dim

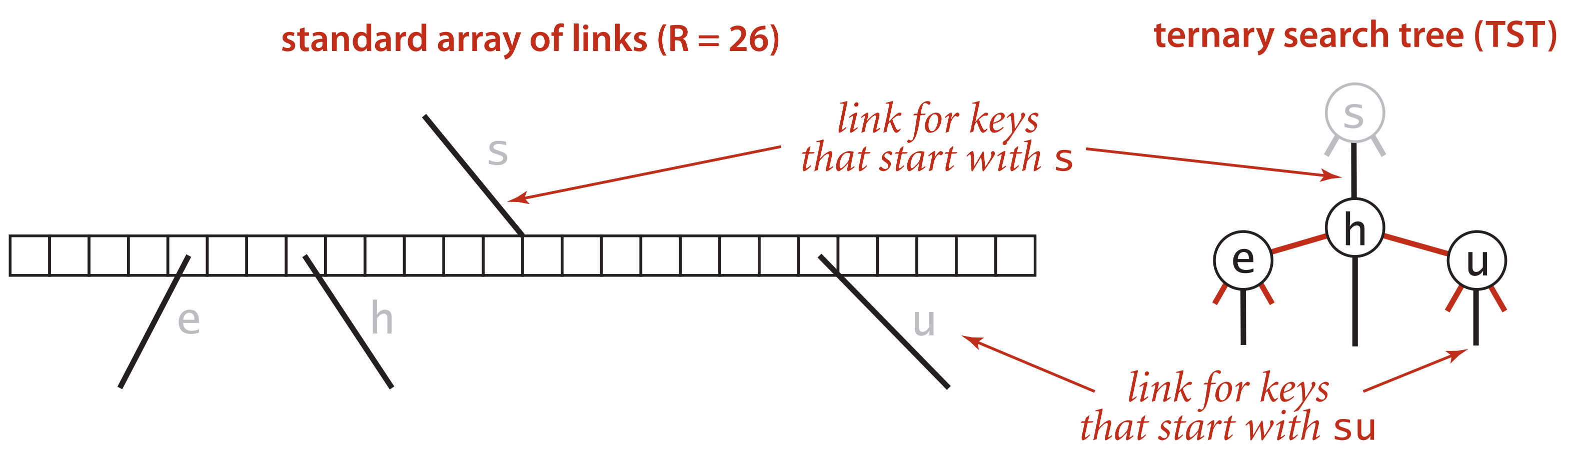
few
jay
owl
joy
rap
gig
wee
was
cab
wad
caw
cue
fee
tap
ago
tar
jam
dug
and
```

TST representation in Java

A TST node is five fields:

- A value.
- A character.
- A reference to a left TST.
- A reference to a middle TST.
- A reference to a right TST.

```
private class Node
{
   private Value val;
   private char c;
   private Node left, mid, right;
}
```



Trie node representations

TST: Java implementation

```
public class TST<Value>
{
   private Node root;
   private class Node
   {  /* see previous slide */  }

   public Value get(String key)
   {  return get(root, key, 0);  }

   private Value get(Node x, String key, int d)
   {
      if (x == null) return null;
      char c = key.charAt(d);
      if      (c < x.c)              return get(x.left,  key, d);
      else if (c > x.c)              return get(x.right, key, d);
      else if (d < key.length() - 1) return get(x.mid,   key, d+1);
      else                           return x.val;
   }

   public void put(String Key, Value val)
   {  /* similar, see book or booksite */  }
}
```

String symbol table implementation cost summary

	character accesses (typical case)				dedup	
implementation	search hit	search miss	insert	space (references)	moby.txt	actors.txt
red-black BST	$L + c \lg^2 n$	$c \lg^2 n$	$c \lg^2 n$	$4n$	1.4	97.4
hashing (linear probing)	L	L	L	$4n$ to $16n$	0.76	40.6
R-way trie	L	$\log_R n$	$R + L$	$(R+1)\, n$	1.12	*out of memory*
TST	$L + \ln n$	$\ln n$	$L + \ln n$	$4n$	0.72	38.7

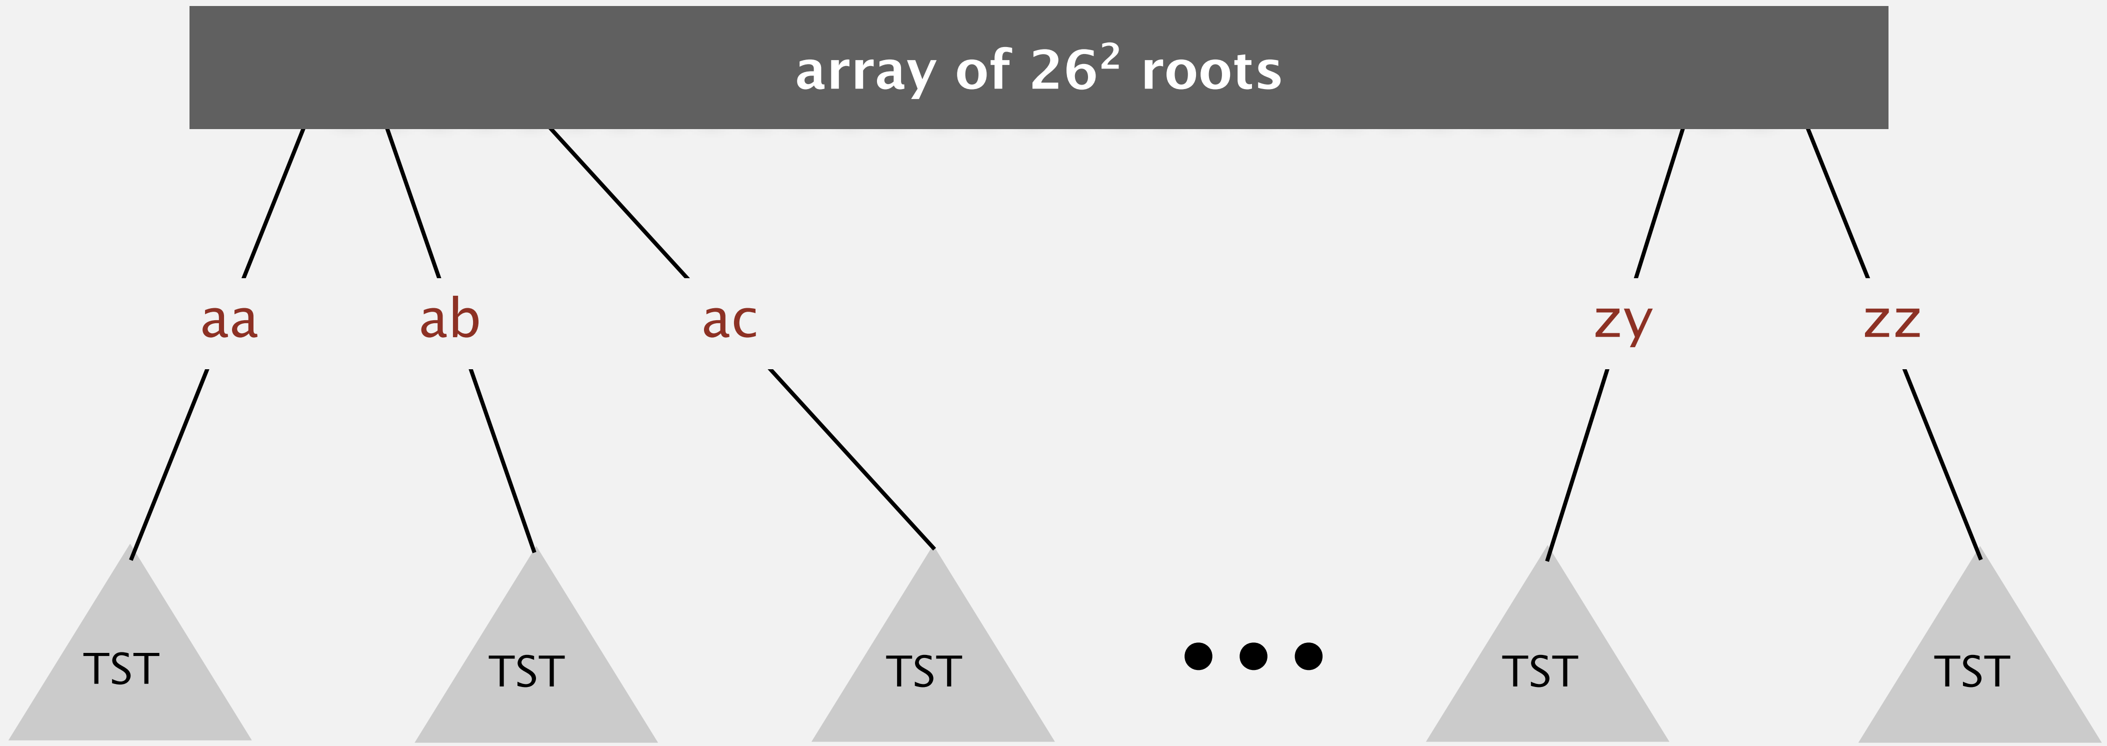
Remark. Can build balanced TSTs via rotations to achieve $L + \log n$ worst-case guarantees.

Bottom line. TST is as fast as hashing (for string keys), space efficient.

TST with R² branching at root

Hybrid of R-way trie and TST.

- Do R^2-way branching at root.
- Each of R^2 root nodes points to a TST.



Q. What about one- and two-letter words?

String symbol table implementation cost summary

	character accesses (typical case)				dedup	
implementation	search hit	search miss	insert	space (references)	moby.txt	actors.txt
red-black BST	$L + c \lg^2 n$	$c \lg^2 n$	$c \lg^2 n$	$4n$	1.4	97.4
hashing (linear probing)	L	L	L	$4n$ to $16n$	0.76	40.6
R-way trie	L	$\log_R n$	$R + L$	$(R+1)\, n$	1.12	*out of memory*
TST	$L + \ln n$	$\ln n$	$L + \ln n$	$4n$	0.72	38.7
TST with R^2	$L + \ln n$	$\ln n$	$L + \ln n$	$4n + R^2$	0.51	32.7

Bottom line. Faster than hashing for our benchmark client.

TST vs. hashing

Hashing.

- Need to examine entire key.
- Search hits and misses cost about the same.
- Performance relies on hash function.
- Does not support ordered symbol table operations.

TSTs.

- Works only for string (or digital) keys.
- Search miss may involve only a few characters.
- Supports ordered symbol table operations (plus extras!).

Bottom line. TSTs are:

- Faster than hashing (especially for search misses).
- More flexible than red-black BSTs. [stay tuned]

https://algs4.cs.princeton.edu

5.2 Tries

- R-way tries
- ternary search tries
- character-based operations

String symbol table API

Character-based operations. The string symbol table API supports several useful character-based operations.

key	value
`by`	4
`sea`	6
`sells`	1
`she`	0
`shells`	3
`shore`	7
`the`	5

Prefix match. Keys with prefix `sh`: `she`, `shells`, and `shore`.

Longest prefix. Key that is the longest prefix of `shellsort`: `shells`.

String symbol table API

public class StringST<Value>		
	StringST()	*create a symbol table with string keys*
void	put(String key, Value val)	*put key-value pair into the symbol table*
Value	get(String key)	*value paired with key*
void	delete(String key)	*delete key and corresponding value*
	⋮	
Iterable<String>	keys()	*all keys*
Iterable<String>	keysWithPrefix(String s)	*keys having s as a prefix*
String	longestPrefixOf(String s)	*longest key that is a prefix of s*

Remark. Can also add other ordered ST methods, e.g., floor() and rank().

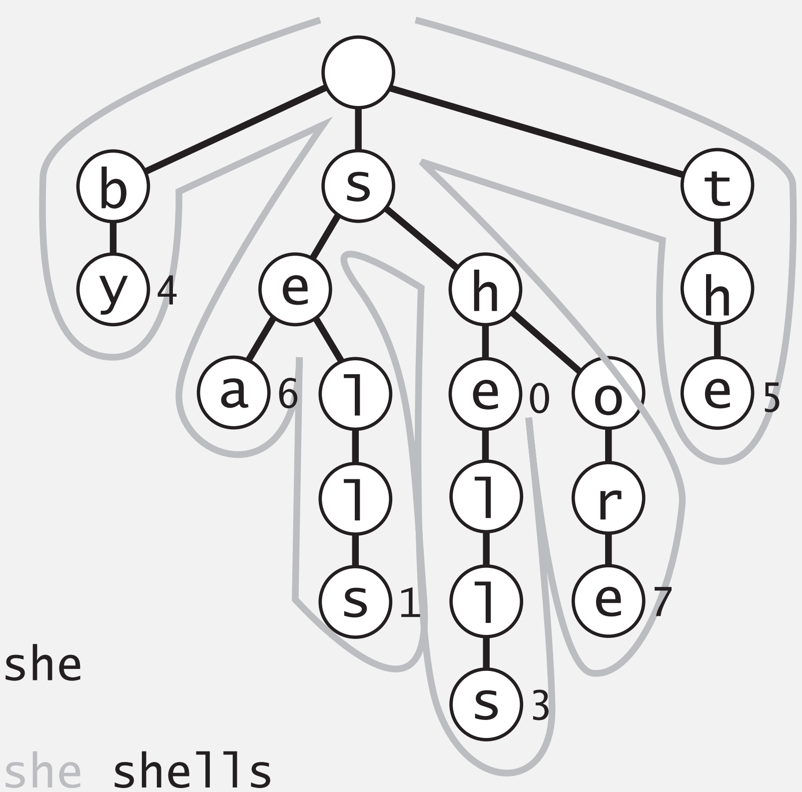
Warmup: ordered iteration

To iterate through all keys in sorted order:

- Do inorder traversal of trie; add keys encountered to a queue.
- Maintain sequence of characters on path from root to node.

keys()

key	queue
b	
by	by
s	
se	
sea	by sea
sel	
sell	
sells	by sea sells
sh	
she	by sea sells she
shell	
shells	by sea sells she shells
sho	
shor	
shore	by sea sells she shells shore
t	
th	
the	by sea sells she shells shore the



Ordered iteration: Java implementation

To iterate through all keys in sorted order:

- Do inorder traversal of trie; add keys encountered to a queue.
- Maintain sequence of characters on path from root to node.

```
public Iterable<String> keys()
{
   Queue<String> queue = new Queue<String>();
   collect(root, "", queue);
   return queue;
}

private void collect(Node x, String prefix, Queue<String> queue)
{
   if (x == null) return;
   if (x.val != null) queue.enqueue(prefix);
   for (char c = 0; c < R; c++)
      collect(x.next[c], prefix + c, queue);
}
```

sequence of characters on path from root to x

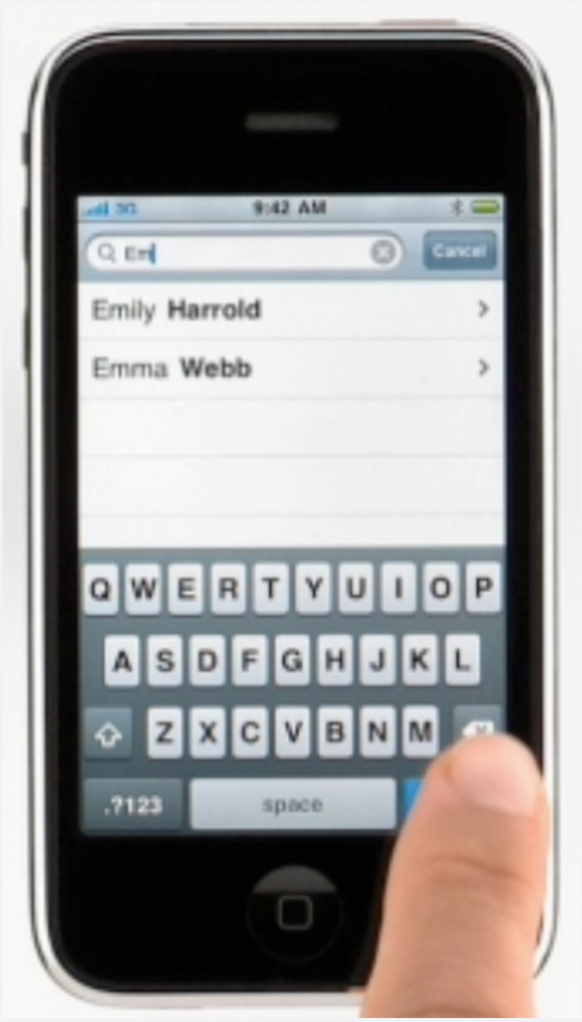
or use `StringBuilder`

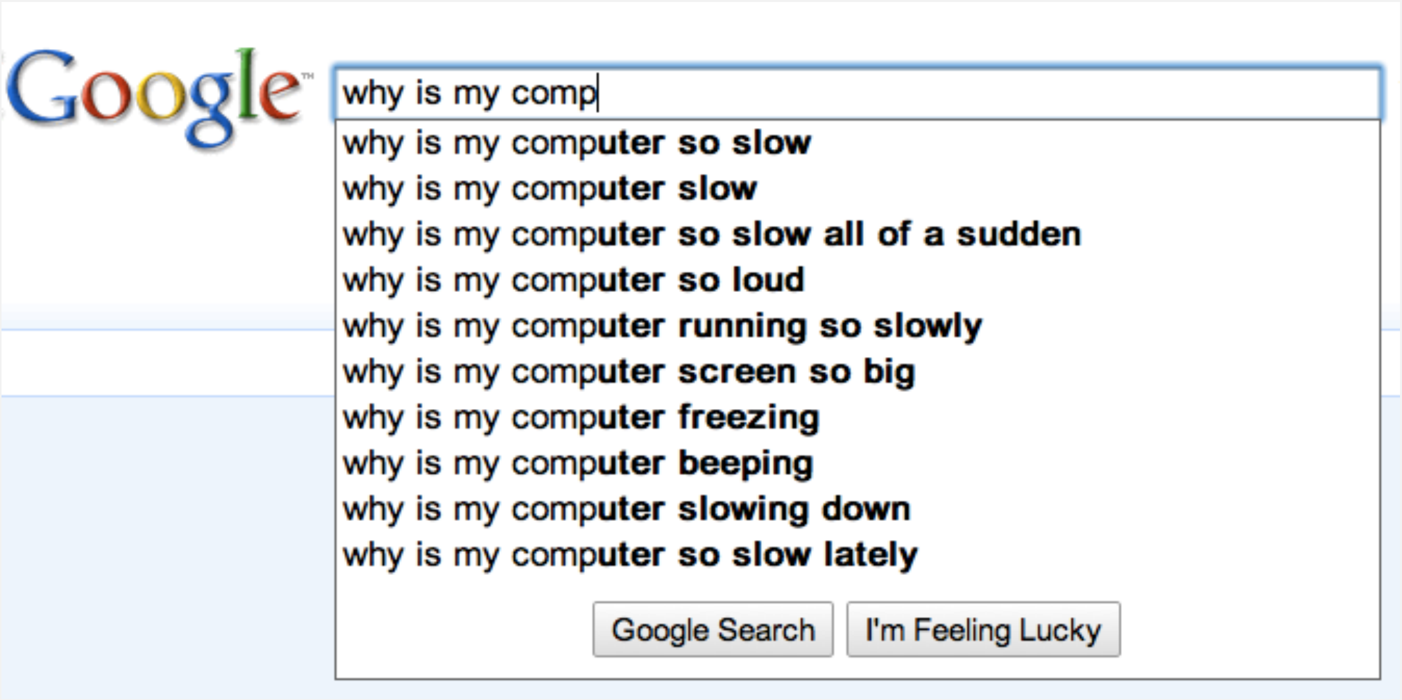
Prefix matches

Find all keys in a symbol table starting with a given prefix.

Ex. Autocomplete in a cell phone, search bar, text editor, or shell.

- User types characters one at a time.
- System reports all matching strings.

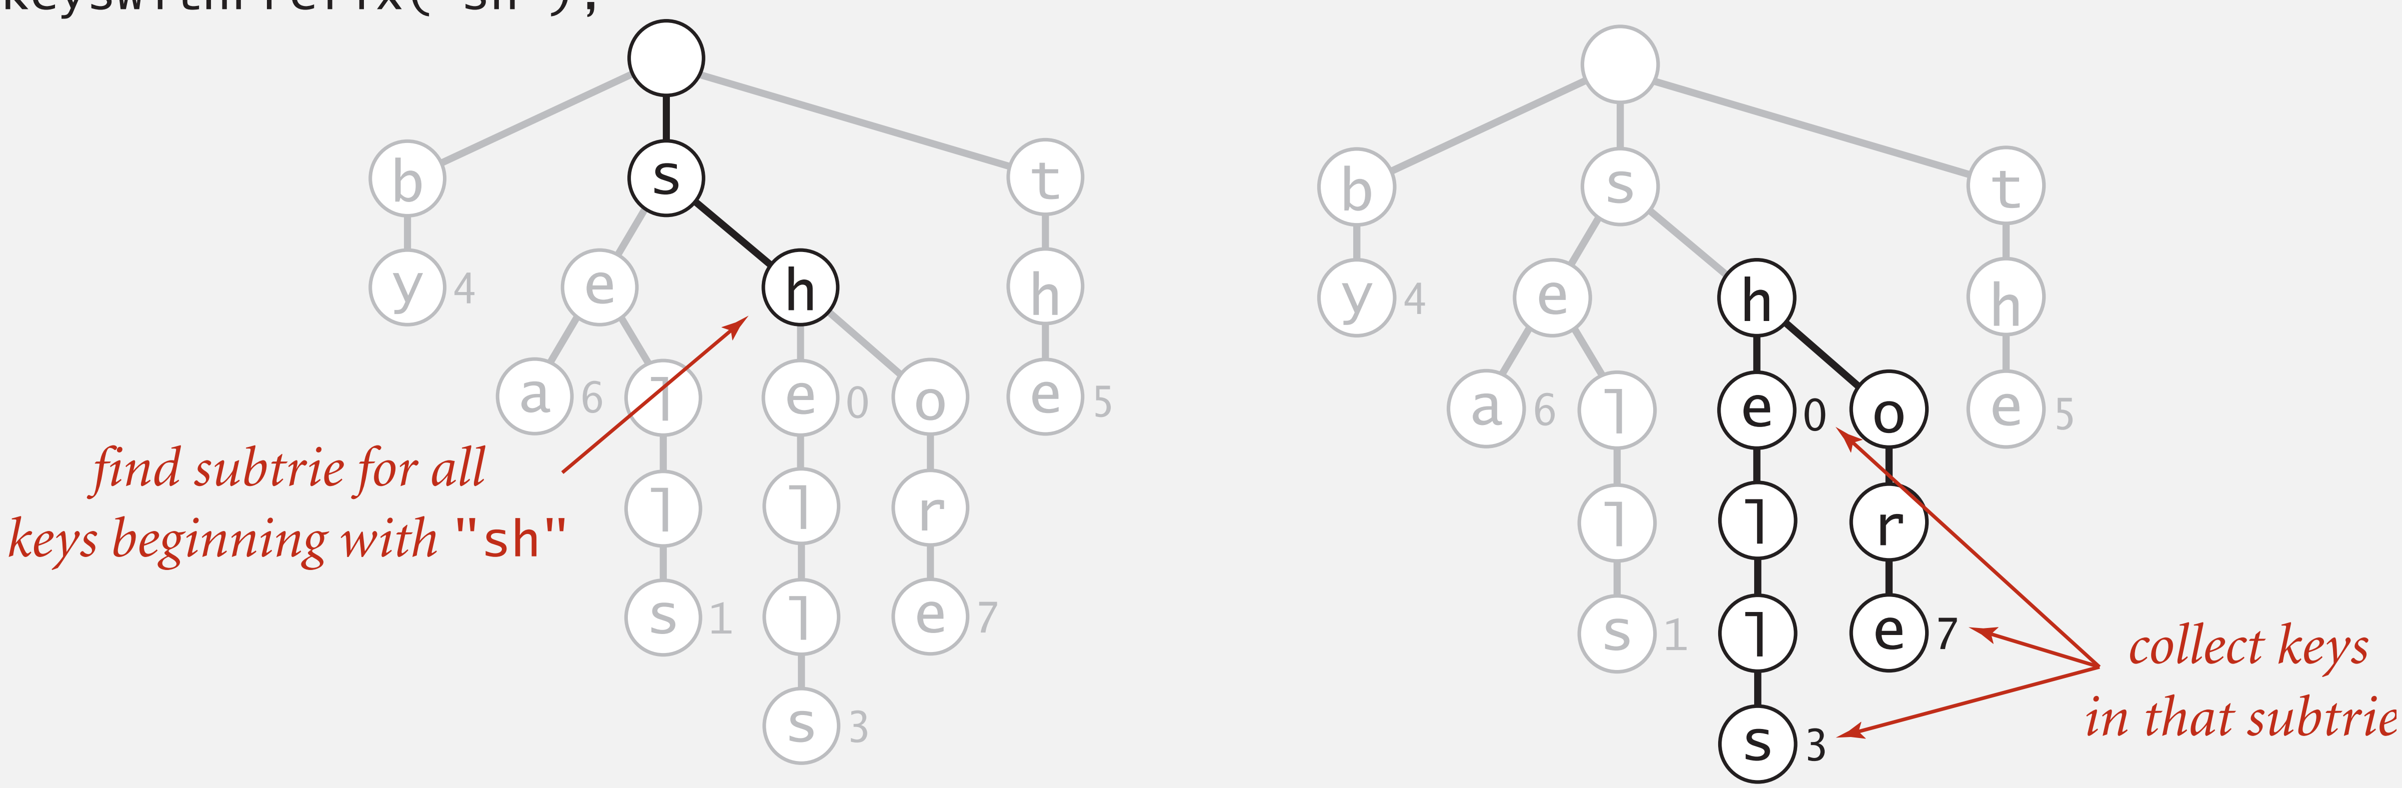




Prefix matches in an R-way trie

Find all keys in a symbol table starting with a given prefix.

```
keysWithPrefix("sh");
```



Longest prefix

Find longest key in symbol table that is a prefix of query string.

Ex 1. To send packet toward destination IP address, router chooses IP address in routing table that is longest prefix match.

```
"128"
"128.112"
"128.112.055"
"128.112.055.15"
"128.112.136"
"128.112.155.11"
"128.112.155.13"
"128.222"
"128.222.136"
```

represented as 32-bit binary number for IPv4 (instead of string)

```
longestPrefixOf("128.112.136.11") = "128.112.136"
longestPrefixOf("128.112.100.16") = "128.112"
longestPrefixOf("128.166.123.45") = "128"
```

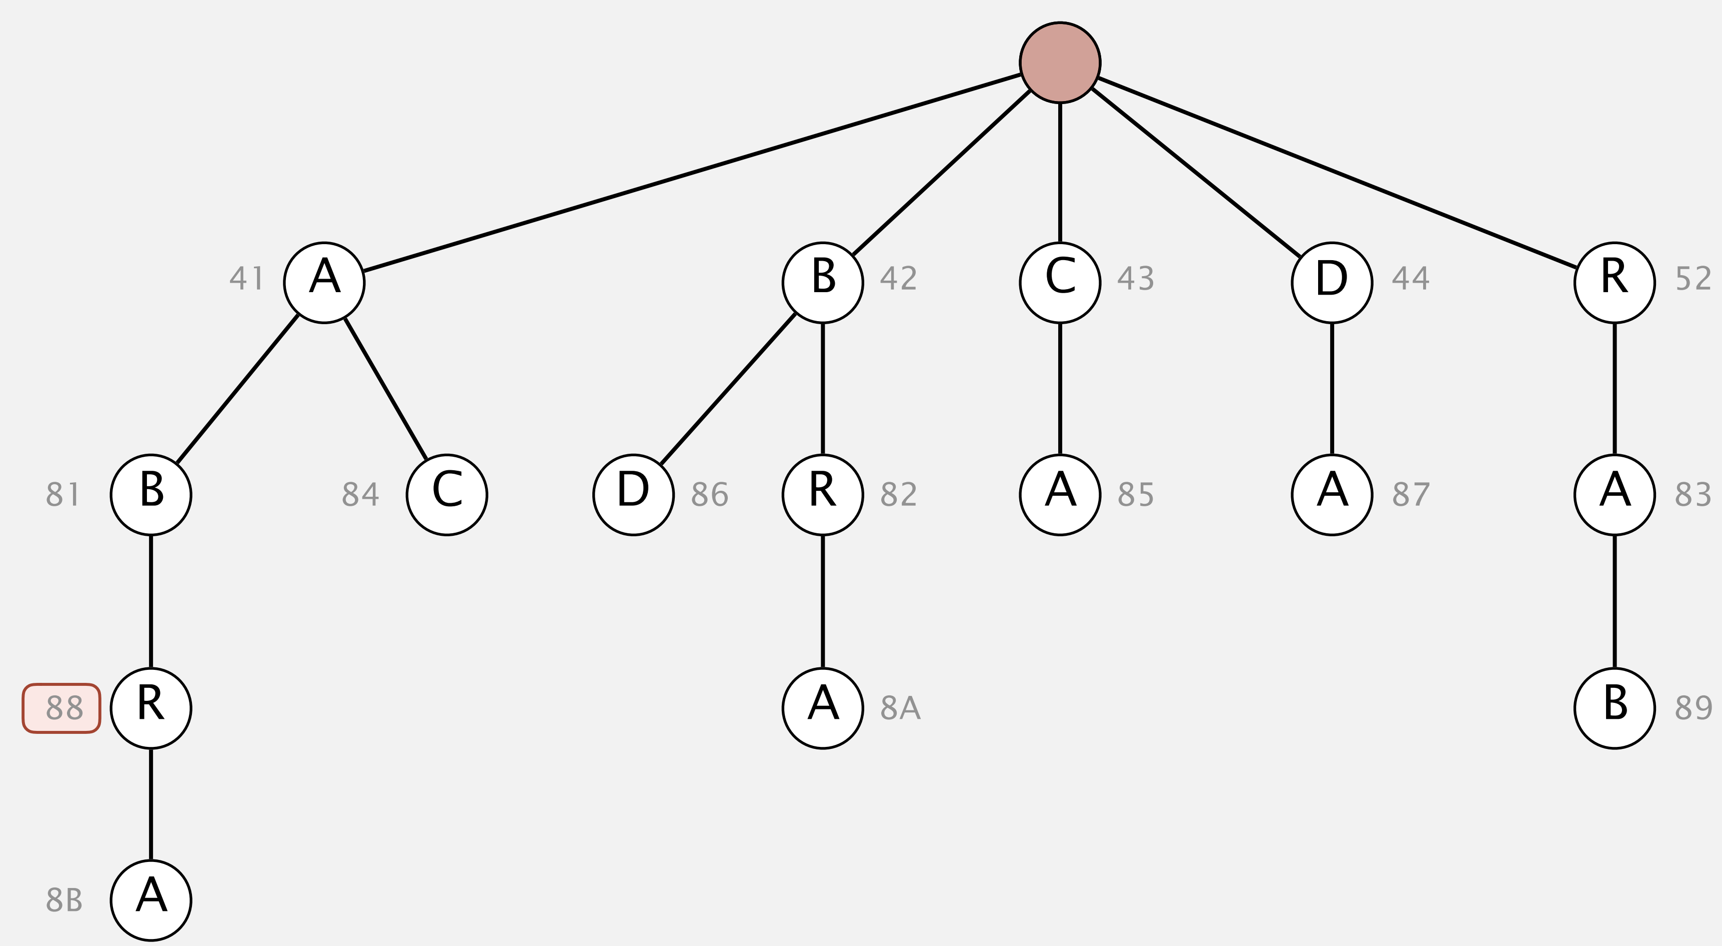
Note. Not the same as floor: `floor("128.112.100.16") = "128.112.055.15"`

Longest prefix

Find longest key in symbol table that is a prefix of query string.

Ex 2. LZW compression.

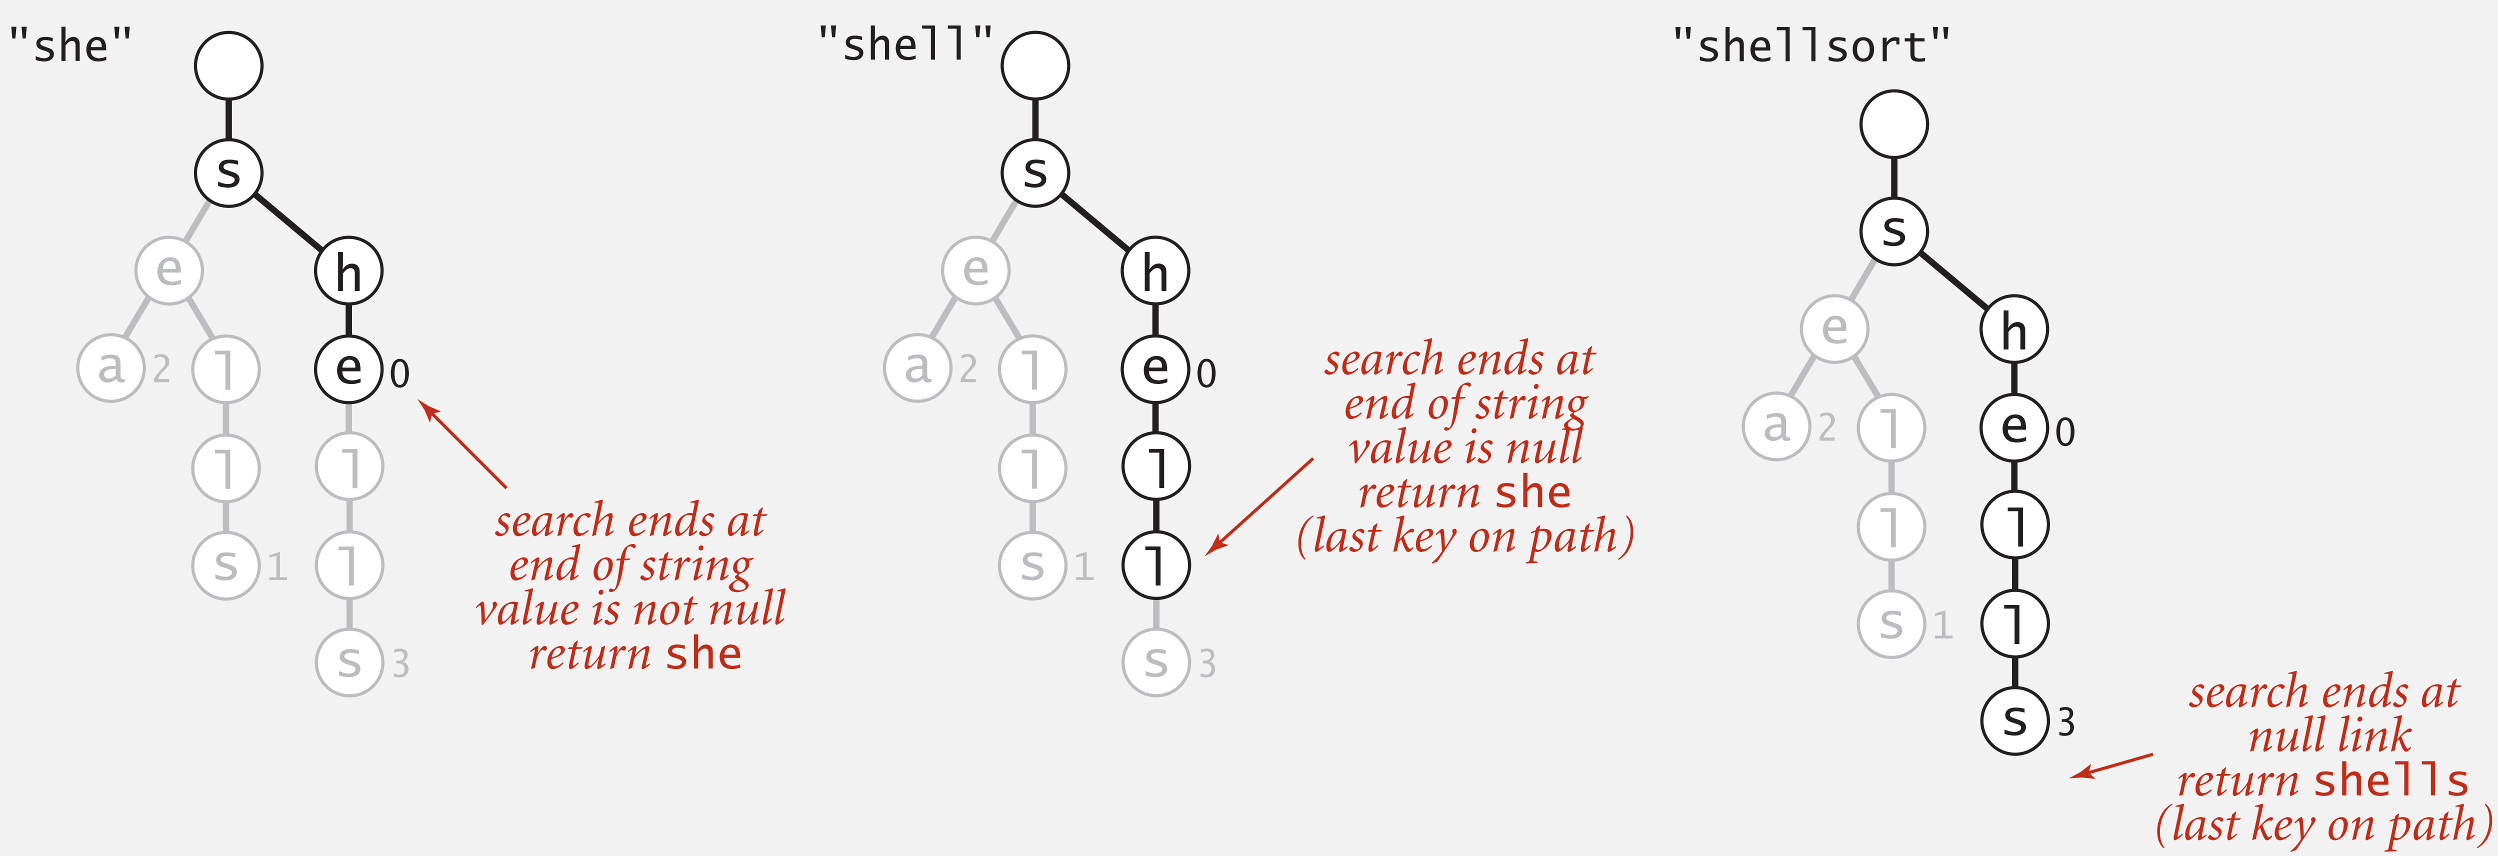
input	…	R	A	B	R	A	B	R	A	B	R	O	C	C	O	L	I	…
value		89		82		88			88									



Longest prefix in an R-way trie

Find longest key in symbol table that is a prefix of query string.

- Search for query string.
- Keep track of longest key encountered.



Possibilities for `longestPrefixOf()`

T9 texting (predictive texting)

Goal. Type text messages on a phone keypad.

Multi-tap input. Enter a letter by repeatedly pressing a key.

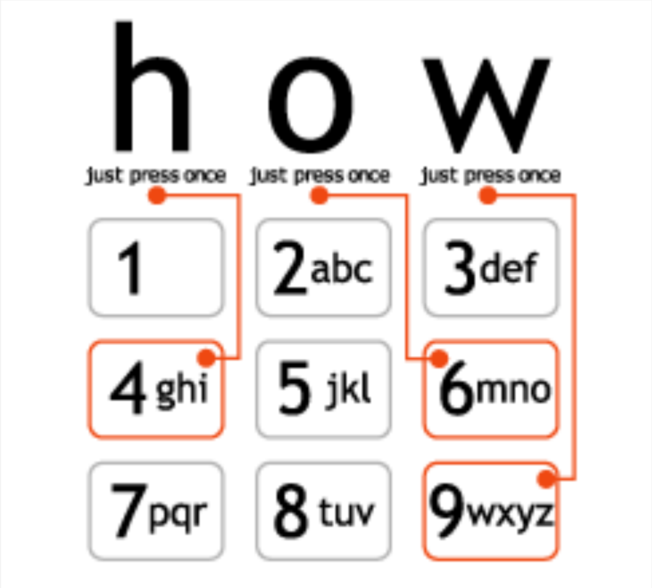
Ex. good: 4 6 6 6 6 6 6 3

"a much faster and more fun way to enter text"

T9 text input.

- Find all words that correspond to given sequence of numbers.

  4663: good, home, gone, hoof. ← textonyms
- Press * to select next option.
- Press 0 to see all completion options.
- System adapts to user's tendencies.



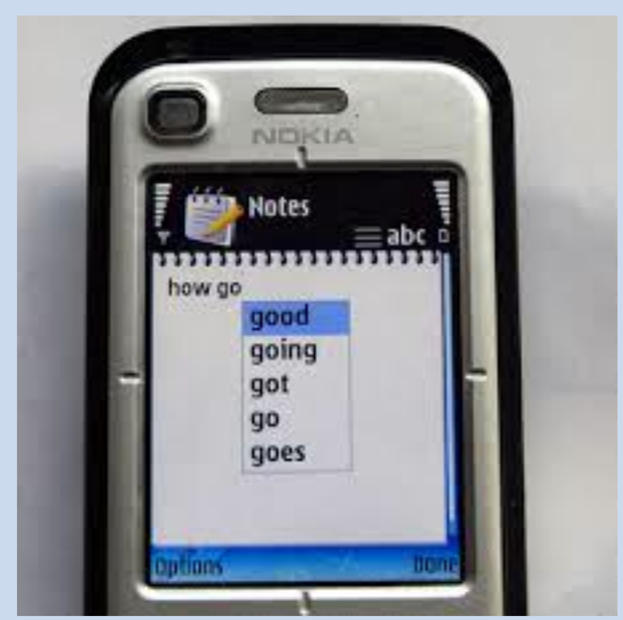
http://www.t9.com

T9 TEXTING

Q. How to implement T9 texting on a mobile phone?

SONY verizon SIEMENS

NEC SANYO SAMSUNG ELECTRONICS



A letter to t9.com

```
To: info@t9support.com
Date: Tue, 25 Oct 2005 14:27:21 -0400 (EDT)

Dear T9 texting folks,

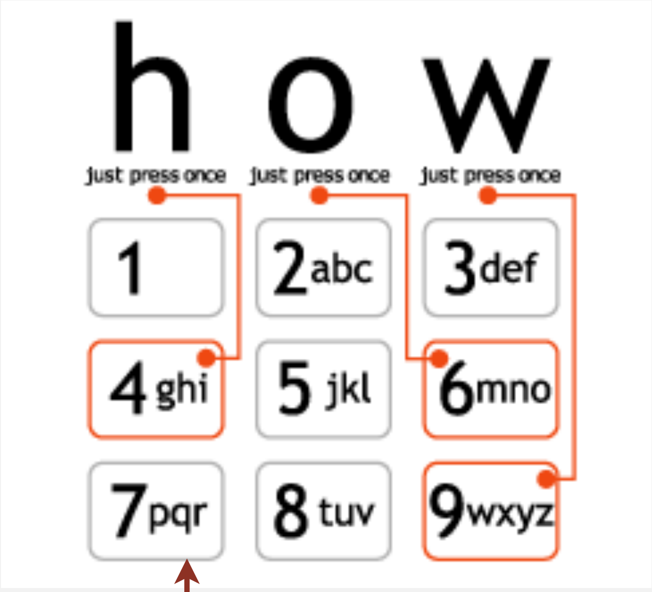
I enjoyed learning about the T9 text system
from your webpage, and used it as an example
in my algorithms and data structures class.
However, one of my students noticed a bug
in your phone keypad

   http://www.t9.com/images/how.gif

Somehow, it is missing the letter 's'. (!)

Just wanted to bring this information to
your attention and thank you for your website.

Regards,
Kevin
```



where the @#$% is the 's' ?

A world without 's' ?

```
To: "'Kevin Wayne'" <wayne@CS.Princeton.EDU>
Date: Tue, 25 Oct 2005 12:44:42 -0700

Thank you Kevin.

I am glad that you find T9 o valuable for your
cla. I had not noticed thi before. Thank for
writing in and letting u know.

Take care,

Brooke nyder

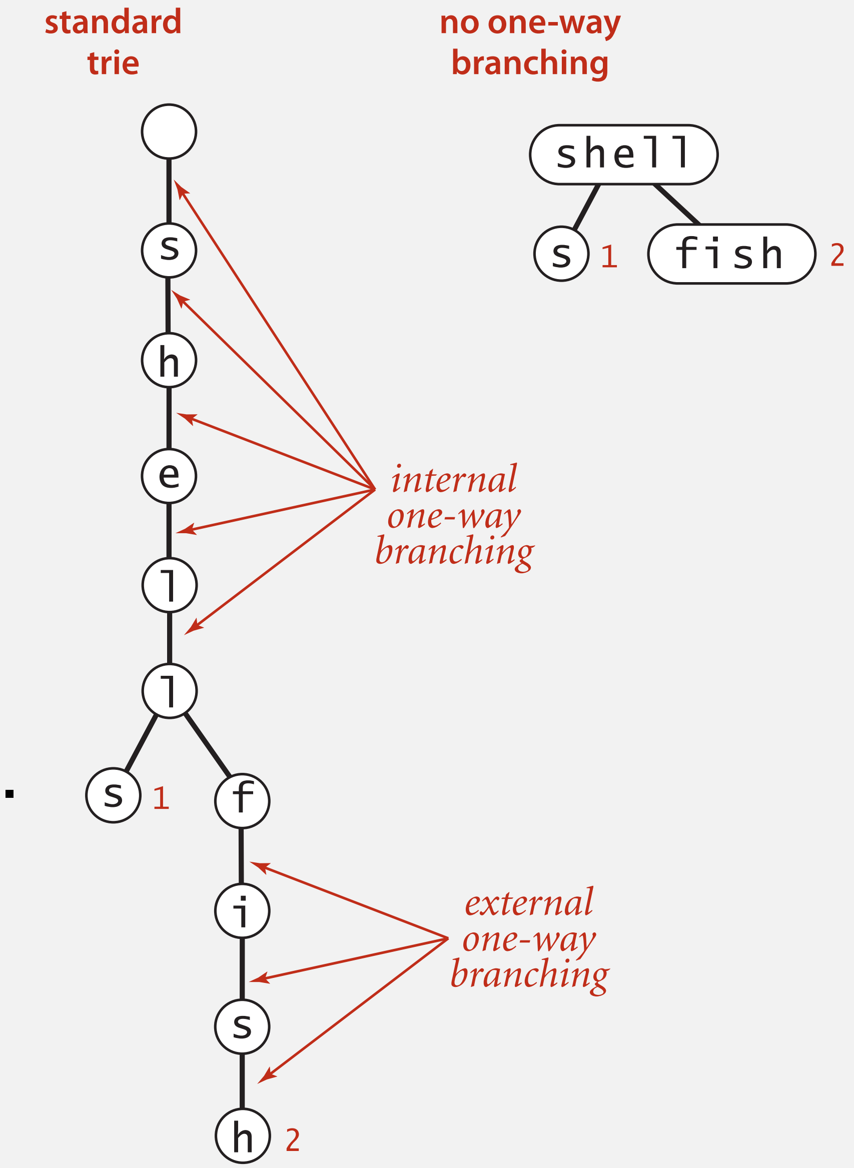
```

Patriciatrie

Patricia trie. [Practical Algorithm to Retrieve Information Coded in Alphanumeric]

- Remove one-way branching.
- Each node represents a sequence of characters.
- Implementation: one step beyond this course.

```
put("shells", 1);
put("shellfish", 2);
```



Applications.

- Database search.
- P2P network search.
- IP routing tables: find longest prefix match.
- Compressed quad-tree for n-body simulation.
- Efficiently storing and querying XML documents.

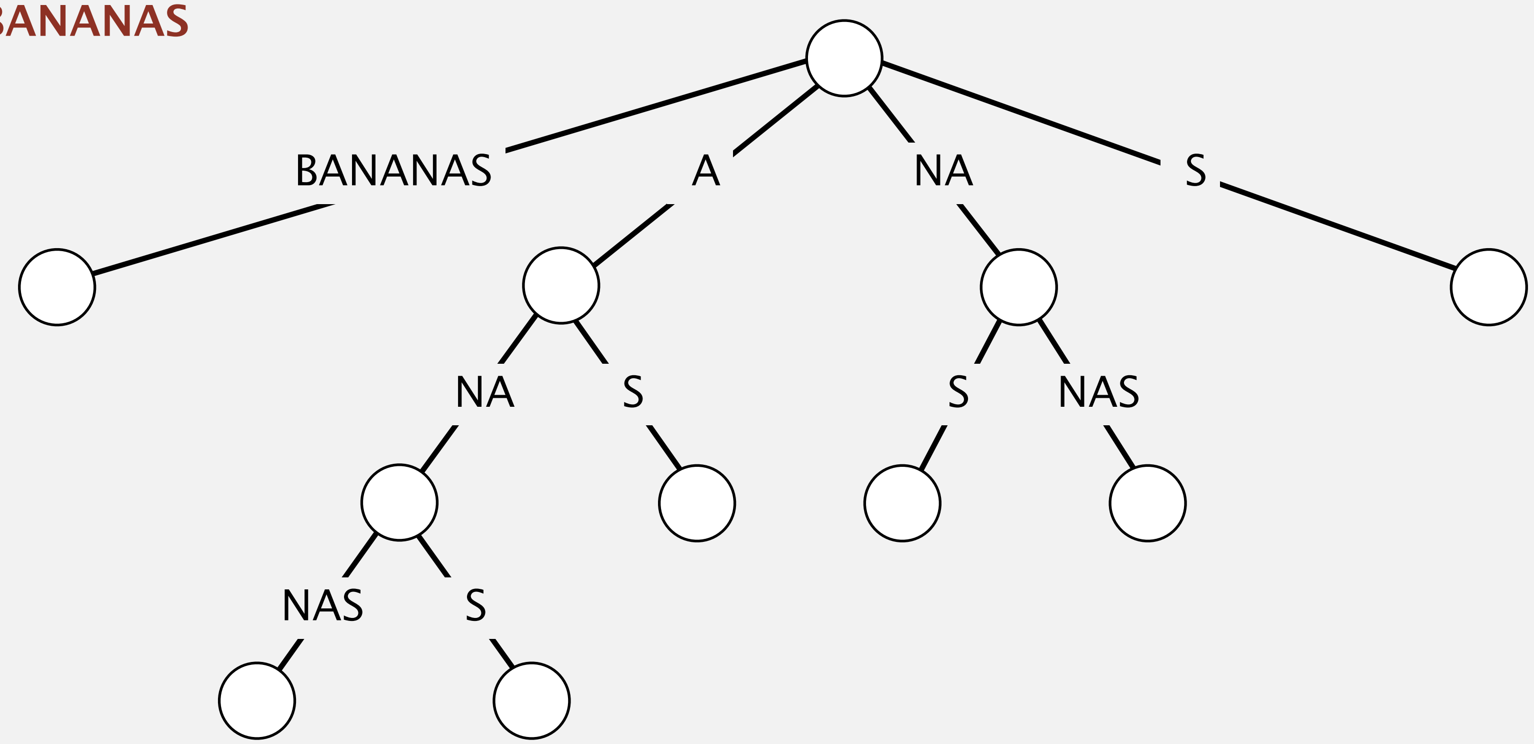
Also known as: crit-bit tree, radix tree.

Suffix tree

Suffix tree.

- Patricia trie of suffixes of a string.
- Linear-time construction: well beyond scope of this course.

suffix tree for BANANAS



Applications.

- Linear-time: longest repeated substring, longest common substring, longest palindromic substring, substring search, tandem repeats, ...
- Computational biology databases (BLAST, FASTA).

String symbol tables summary

A success story in algorithm design and analysis.

Red–black BST.

- Performance guarantee: $\log n$ key compares.
- Supports ordered symbol table API.

Hash tables.

- Performance guarantee: constant number of probes.
- Requires good hash function for key type.

Tries. R-way, TST.

- Performance guarantee: $\log n$ characters accessed.
- Supports character-based operations.
