## A motivating example

Install minimum number of paving stones to connect all of the houses.

# Spanning tree

---

**Def.** A **spanning tree** of  $G$  is a subgraph  $T$  that is:

- A tree: connected and acyclic.
- Spanning: includes all of the vertices.

graph  $G$

spanning tree  $T$

# Spanning tree

---

**Def.** A **spanning tree** of  $G$  is a subgraph  $T$  that is:

- A tree: connected and acyclic.
- Spanning: includes all of the vertices.

not connected

# Spanning tree

---

**Def.** A **spanning tree** of  $G$  is a subgraph  $T$  that is:

- A tree: connected and acyclic.
- Spanning: includes all of the vertices.

not acyclic

# Spanning tree

---

**Def.** A **spanning tree** of  $G$  is a subgraph  $T$  that is:

- Spanning: includes all of the vertices.

not spanning

# Minimum spanning tree problem

---

**Input.** Connected, undirected graph  $G$  with positive edge weights.

# Minimum spanning tree problem

---

**Input.** Connected, undirected graph  $G$  with positive edge weights.

**Output.** A spanning tree of minimum weight.

**minimum spanning tree T**  
(weight = 50 = 4 + 6 + 5 + 8 + 9 + 11 + 7)

**Brute force.** Try all spanning trees?

Let  $T$  be any spanning tree of a connected graph  $G$  with  $V$  vertices.  
Which of the following properties must hold?

- A. Removing any edge from  $T$  disconnects it.
- B. Adding any edge to  $T$  creates a cycle.
- C.  $T$  contains exactly  $V - 1$  edges.
- D. All of the above.

spanning tree  $T$  of graph  $G$

# Network design

**Network.** Vertex = network component; edge = potential connection; edge weight = cost.

electrical, computer, telecommunication, transportation

# Hierarchical clustering

**Microarray graph.** Vertex = cancer tissue; edge = all pairs; edge weight = dissimilarity.

## 4.3 MINIMUM SPANNING TREES

---

- *introduction*
- *cut property*
- *edge-weighted graph API*
- *Kruskal's algorithm*
- *Prim's algorithm*

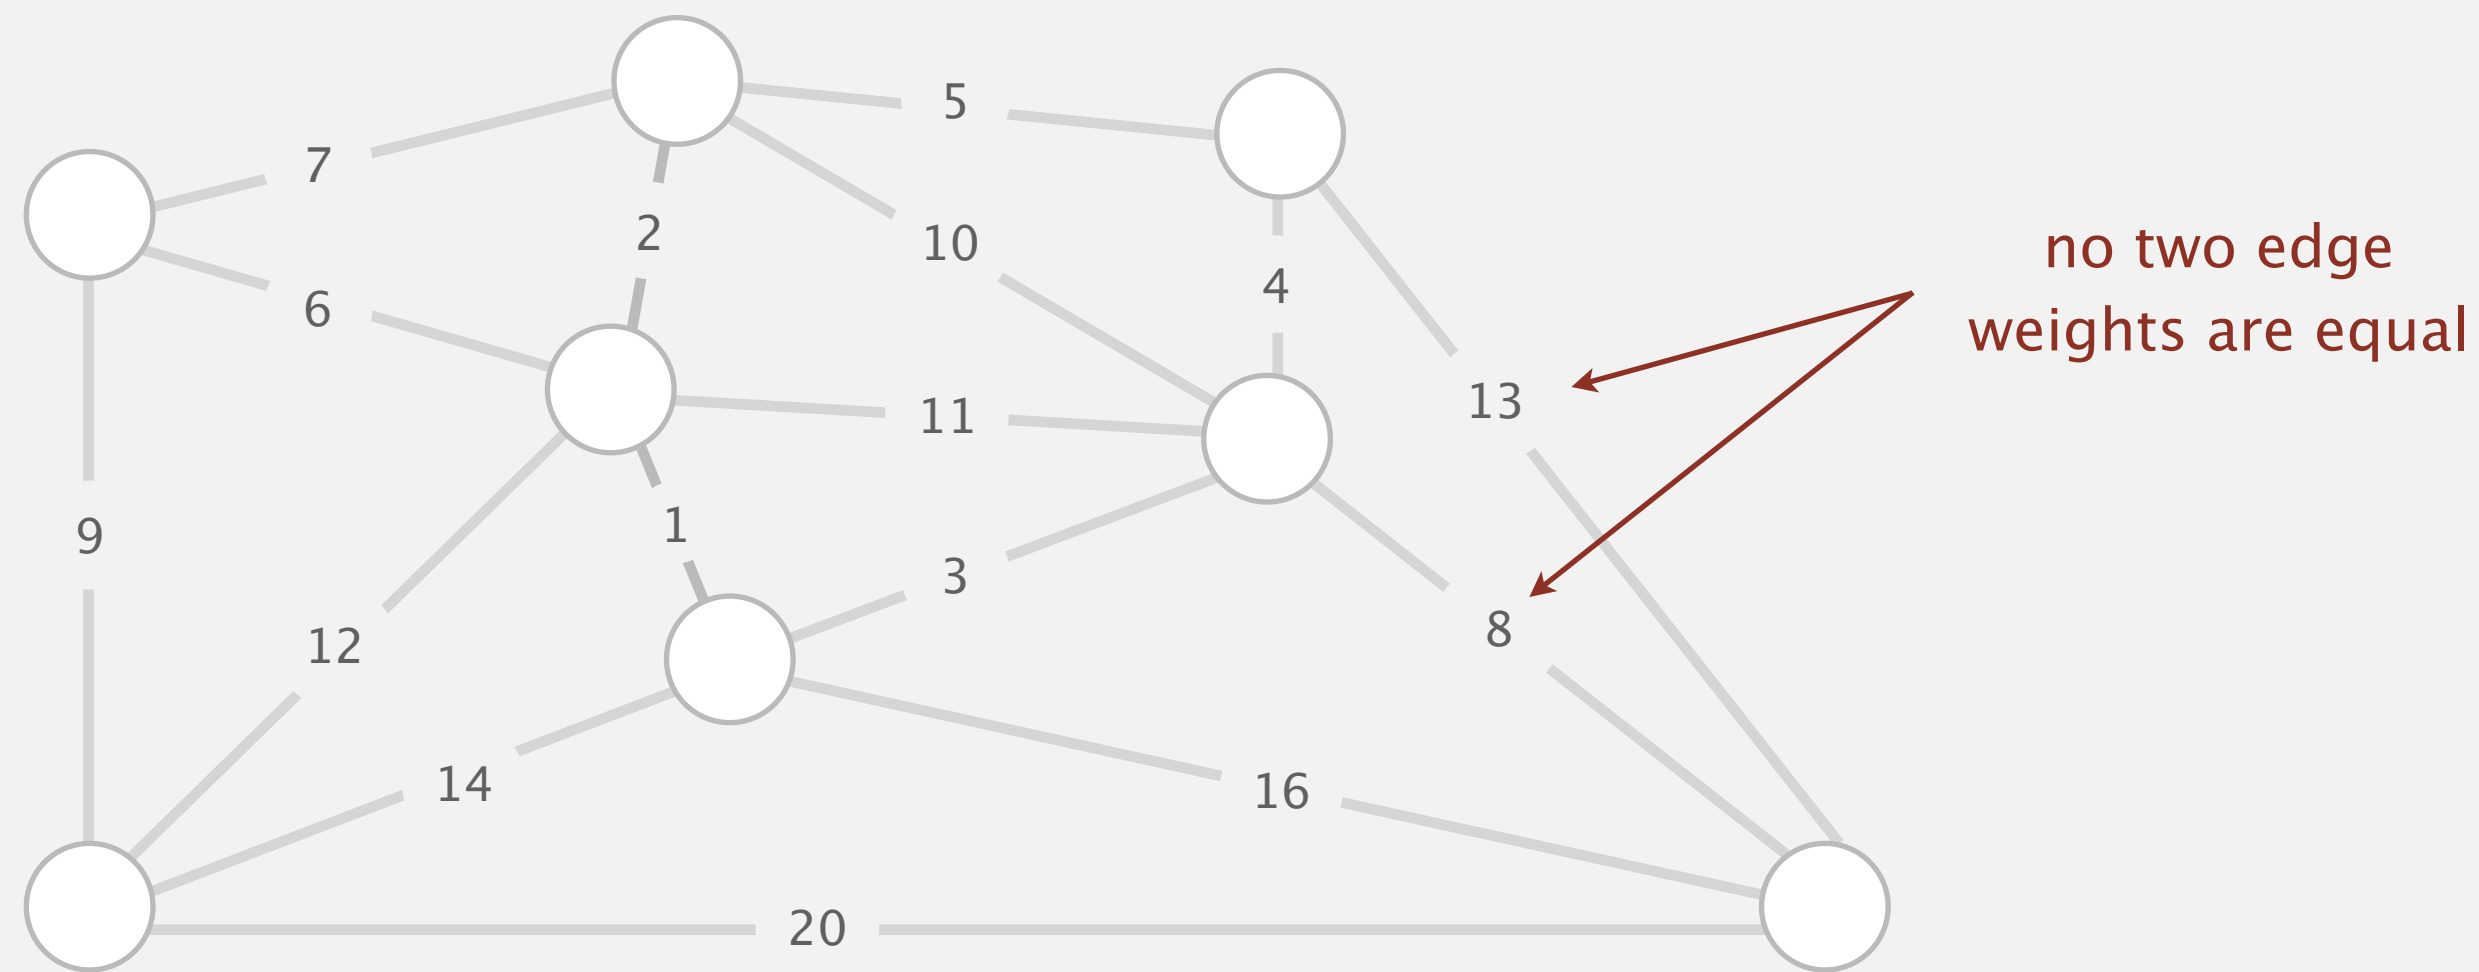

## Simplifying assumptions

For simplicity, we assume:

- The graph is connected.  $\Rightarrow$  MST exists.
- The edge weights are distinct.  $\Rightarrow$  MST is unique.  $\longleftarrow$  see Exercise 4.3.3 (solved on booksite)

**Note.** Today's algorithms all work fine with duplicate edge weights.

assumption simplifies the analysis

# Cut property

**Def.** A **cut** in a graph is a partition of its vertices into two nonempty sets.

**Def.** A **crossing edge** of a cut is an edge that has one endpoint in each set.

**Cut property.** For any cut, its min-weight crossing edge is in the MST.

# Cut property

**Def.** A **cut** in a graph is a partition of its vertices into two nonempty sets.

**Def.** A **crossing edge** of a cut is an edge that has one endpoint in each set.

**Cut property.** For any cut, its min-weight crossing edge is in the MST.

**Note.** A cut may have multiple edges in the MST.

Which is the min-weight edge crossing the cut  $\{ 2, 3, 5, 6 \}$  ?

A. 0–7 (0.16)

B. 2–3 (0.17)

C. 0–2 (0.26)

D. 5–7 (0.28)

0–7 0.16

2–3 0.17

1–7 0.19

0–2 0.26

5–7 0.28

1–3 0.29

1–5 0.32

6–0 0.58

6–4 0.93

# Cut property: correctness proof

**Def.** A **cut** in a graph is a partition of its vertices into two nonempty sets.

**Def.** A **crossing edge** of a cut is an edge that has one endpoint in each set.

**Cut property.** For any cut, its min-weight crossing edge  $e$  is in the MST.

**Pf.** [by contradiction] Suppose  $e$  is not in the MST  $T$ .

- Adding  $e$  to  $T$  creates a unique cycle.
- Some other edge  $f$  in cycle must also be a crossing edge.
- Removing  $f$  and adding  $e$  to  $T$  yields a different spanning tree  $T'$ .
- Since  $weight(e) < weight(f)$ , we have  $weight(T') < weight(T)$ .
- Contradiction. ▀

# Framework for minimum spanning tree algorithms

---

## Generic algorithm (to compute MST in $G$ )

---

$T = \emptyset$ .

Repeat until  $T$  is a spanning tree:  $\longleftarrow V - 1$  edges

- Find a cut in  $G$ .
  - $e \leftarrow$  min-weight crossing edge.
  - $T \leftarrow T \cup \{e\}$ .
- 

## Efficient implementations.

- Which cut?  $\longleftarrow 2^{V-2}$  distinct cuts
- How to compute min-weight crossing edge?

Ex 1. Kruskal's algorithm.

Ex 2. Prim's algorithm.

Ex 3. Borůvka's algorithm.

# Weighted edge API

---

**API.** Edge abstraction for weighted edges.

```
public class Edge implements Comparable<Edge>
```

```
    Edge(int v, int w, double weight)    create a weighted edge v-w
```

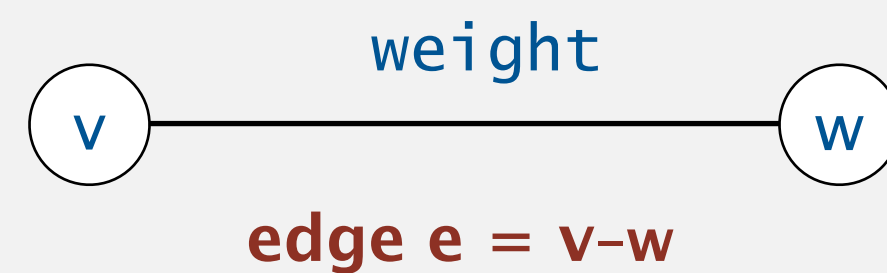

```
    int either()                        either endpoint
```

```
    int other(int v)                   the endpoint that's not v
```

```
    int compareTo(Edge that)           compare edges by weight
```

```
    ⋮
```

```
    ⋮
```

Idiom for processing an edge  $e$ . `int v = e.either(), w = e.other(v).`

# Weighted edge: Java implementation

```
public class Edge implements Comparable<Edge>
{
    private final int v, w;
    private final double weight;
```

```
    public Edge(int v, int w, double weight)
    {
        this.v = v;
        this.w = w;
        this.weight = weight;
    }
```

← constructor

```
    public int either()
    { return v; }
```

← either endpoint

```
    public int other(int vertex)
    {
        if (vertex == v) return w;
        else return v;
    }
```

← other endpoint

```
    public int compareTo(Edge that)
    { return Double.compare(this.weight, that.weight); }
```

← compare edges  
by weight

```
}
```

# Edge-weighted graph API

---

**API.** Same as [Graph](#) and [Digraph](#), except with explicit [Edge](#) objects.

```
public class EdgeWeightedGraph
```

```
    EdgeWeightedGraph(int V)           create an empty graph with V vertices
```

```
    void addEdge(Edge e)               add weighted edge e to this graph
```

```
    Iterable<Edge> adj(int v)           edges incident to v
```

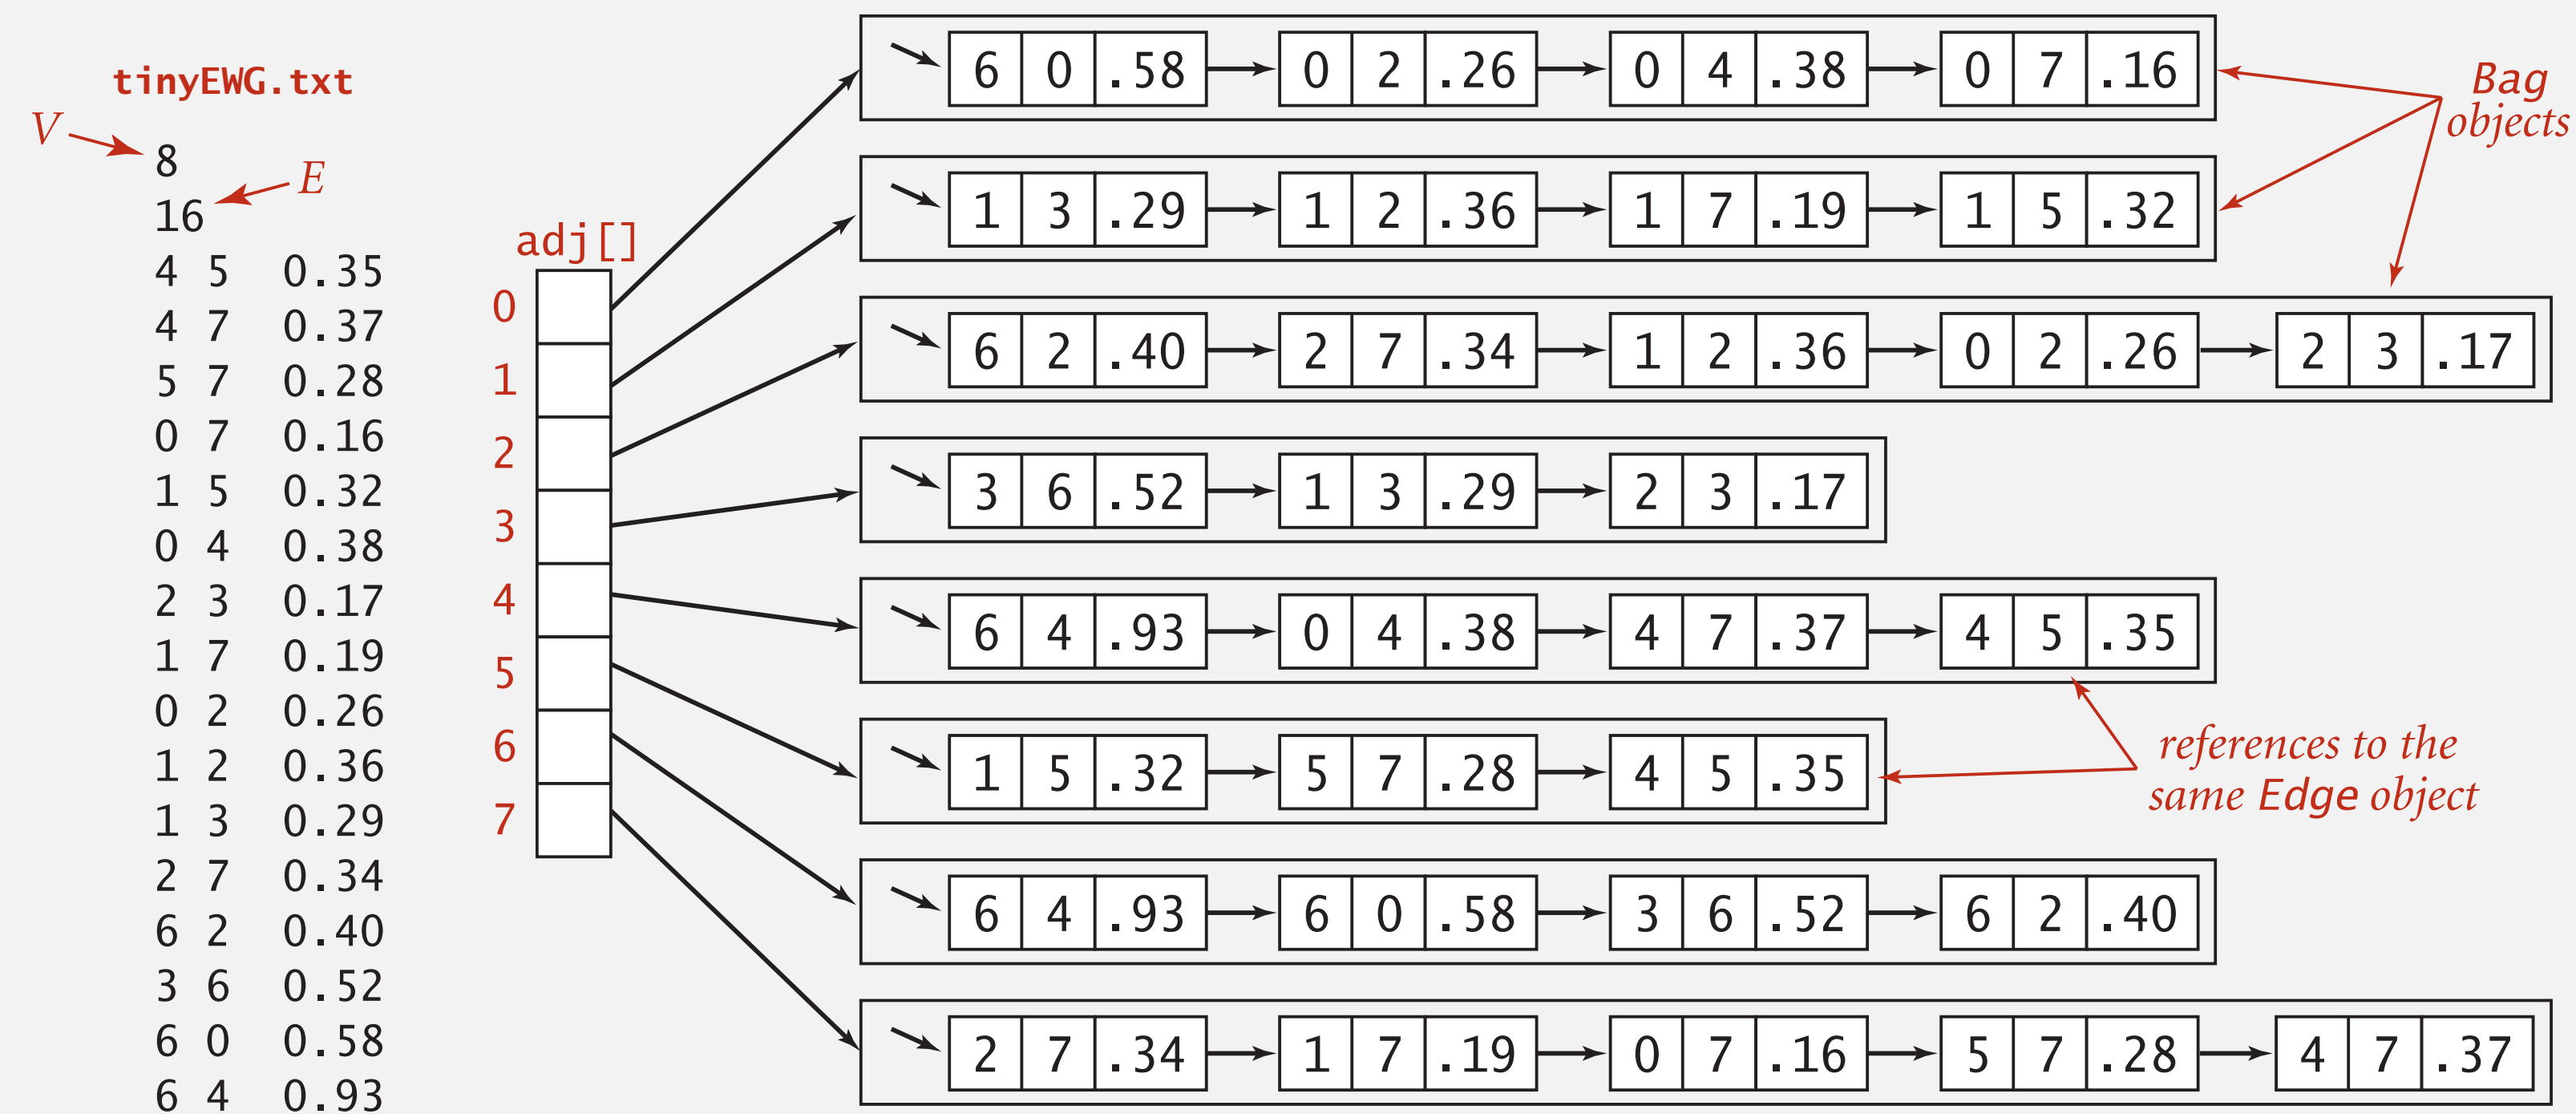

```
    ⋮
```

```
    ⋮
```

# Edge-weighted graph: adjacency-lists representation

Representation. Maintain vertex-indexed array of Edge lists.

# Edge-weighted graph: adjacency-lists implementation

```
public class EdgeWeightedGraph
{
    private final int V;
    private final Bag<Edge>[] adj;
```

← same as Graph (but adjacency lists of Edge objects)

```
    public EdgeWeightedGraph(int V)
    {
        this.V = V;
        adj = (Bag<Edge>[]) new Bag[V];
        for (int v = 0; v < V; v++)
            adj[v] = new Bag<>();
    }
```

← constructor

```
    public void addEdge(Edge e)
    {
        int v = e.either(), w = e.other(v);
        adj[v].add(e);
        adj[w].add(e);
    }
```

← add same Edge object to both adjacency lists

```
    public Iterable<Edge> adj(int v)
    { return adj[v]; }
```

```
}
```

# Minimum spanning tree API

---

Q. How to represent the MST?

A. Technically, an MST is an edge-weighted graph.  
For convenience, we represent it as a set of edges.

public class MST		
MST(EdgeWeightedGraph G)		constructor
Iterable<Edge> edges()		edges in MST
double weight()		weight of MST

## 4.3 MINIMUM SPANNING TREES

---

- *introduction*
- *cut property*
- *edge-weighted graph API*
- ***Kruskal's algorithm***
- *Prim's algorithm*

# Kruskal's algorithm demo

Consider edges in ascending order of weight.

- Add next edge to  $T$  unless doing so would create a cycle.

an edge-weighted graph

graph edges  
sorted by weight

↓

0-7	0.16

1-5	0.32
2-7	0.34
4-5	0.35
1-2	0.36
4-7	0.37
0-4	0.38
6-2	0.40
3-6	0.52
6-0	0.58
6-4	0.93

In which order does Kruskal's algorithm select edges in MST?

**A.** 1, 2, 4, 5, 6

**B.** 1, 2, 4, 5, 8

**C.** 1, 2, 5, 4, 8

**D.** 8, 2, 1, 5, 4

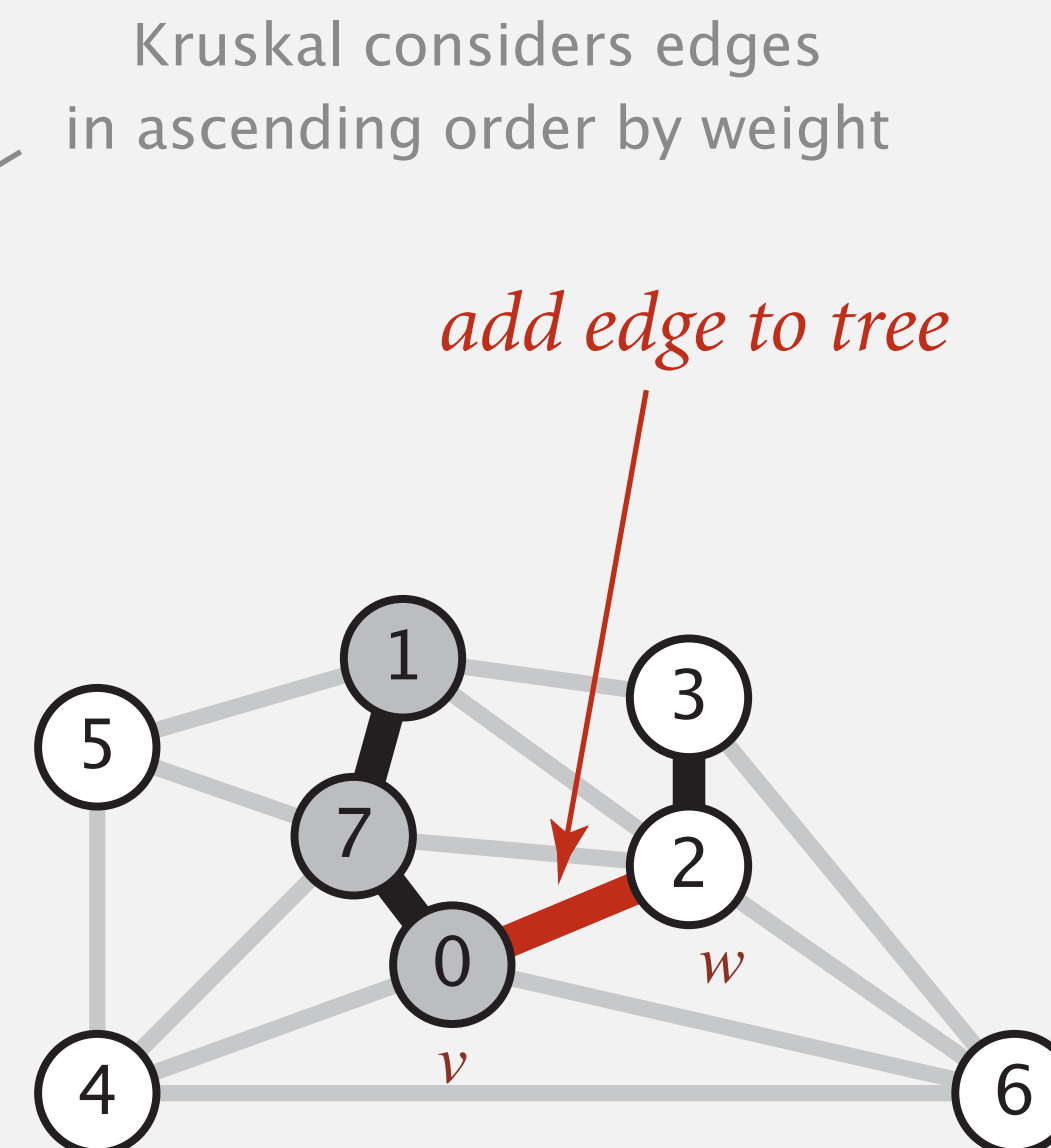

# Kruskal's algorithm: correctness proof

**Proposition.** [Kruskal 1956] Kruskal's algorithm computes the MST.

**Pf.** Kruskal's algorithm adds edge  $e$  to  $T$  if and only if  $e$  is in the MST.

[Case 1  $\Rightarrow$ ] Kruskal's algorithm adds edge  $e = v-w$  to  $T$ .

- Vertices  $v$  and  $w$  are in different connected components of  $T$ .
- Cut = set of vertices connected to  $v$  in  $T$ .
- By construction of cut,  $e$  is a crossing edge and no crossing edge
  - is currently in  $T$
  - was considered by Kruskal before  $e$
- Thus,  $e$  is a min weight crossing edge.
- Cut property  $\Rightarrow e$  is in the MST.

# Kruskal's algorithm: correctness proof

**Proposition.** [Kruskal 1956] Kruskal's algorithm computes the MST.

**Pf.** Kruskal's algorithm adds edge  $e$  to  $T$  if and only if  $e$  is in the MST.

[Case 2  $\Leftarrow$ ] Kruskal's algorithm discards edge  $e = v-w$ .

- From Case 1, all edges currently in  $T$  are in the MST.
- The MST can't contain a cycle, so it can't also contain  $e$ . ■

# Kruskal's algorithm: implementation challenge

**Challenge.** Would adding edge  $v-w$  to  $T$  create a cycle? If not, add it.

**Efficient solution.** Use the **union-find** data structure.

- Maintain a set for each **connected component** in  $T$ .
- If  $v$  and  $w$  are in same set, then adding  $v-w$  to  $T$  would create a cycle. [Case 2]
- Otherwise, add  $v-w$  to  $T$  and merge sets containing  $v$  and  $w$ . [Case 1]

Case 2: adding  $v-w$  creates a cycle

Case 1: add  $v-w$  to  $T$  and merge sets containing  $v$  and  $w$

# Kruskal's algorithm: Java implementation

```
public class KruskalMST
{
    private Queue<Edge> mst = new Queue<>();

    public KruskalMST(EdgeWeightedGraph G)
    {
        Edge[] edges = G.edges();
        Arrays.sort(edges);
        UF uf = new UF(G.V());

        for (int i = 0; i < G.E(); i++)
        {
            Edge e = edges[i];
            int v = e.either(), w = e.other(v);
            if (uf.find(v) != uf.find(w))
            {
                mst.enqueue(e);
                uf.union(v, w);
            }
        }
    }

    public Iterable<Edge> edges()
    {
        return mst;
    }
}
```

← edges in the MST

← sort edges by weight

← maintain connected components

← optimization: stop as soon as  $V-1$  edges in  $T$

← greedily add edges to MST

← edge  $v-w$  does not create cycle

← add edge  $e$  to MST

← merge connected components

# Kruskal's algorithm: running time

---

**Proposition.** In the worst case, Kruskal's algorithm computes the MST in an edge-weighted graph in  $\Theta(E \log E)$  time and  $\Theta(E)$  extra space.

**Pf.**

- Bottlenecks are sort and union-find operations.

operation	frequency	time per op
<b>SORT</b>	1	$E \log E$
<b>UNION</b>	$V - 1$	$\log V^\dagger$
<b>FIND</b>	$2 E$	$\log V^\dagger$

$\dagger$  using weighted quick union

- Total.  $\Theta(V \log V) + \Theta(E \log V) + \Theta(E \log E)$ .

dominated by  $\Theta(E \log E)$   
since graph is connected

Given a graph with positive edge weights, how to find a spanning tree that minimizes the sum of the squares of the edge weights?

- A. Run Kruskal's algorithm using the **original** edge weights.
- B. Run Kruskal's algorithm using the **squares** of the edge weights.
- C. Run Kruskal's algorithm using the **square roots** of the edge weights.
- D. All of the above.

$$\text{sum of squares} = 4^2 + 6^2 + 5^2 + 10^2 + 11^2 + 7^2 = 347$$

# MAXIMUM SPANNING TREE

**Problem.** Given an undirected graph  $G$  with positive edge weights, find a spanning tree that **maximizes the sum** of the edge weights.

**Goal.** Design algorithm that takes  $\Theta(E \log E)$  time in the worst case.

maximum spanning tree T (weight = 104)

**Greedy algorithm.** Make a locally optimal and irreversible choice at each step of algorithm.

with the hope of finding a global optimum

## 4.3 MINIMUM SPANNING TREES

6-4	0.93

# Prim's algorithm: lazy implementation

**Challenge.** How to efficiently find min-weight edge with exactly one endpoint in  $T$ ?

**Lazy solution.** Maintain a PQ of **edges** with (at least) one endpoint in  $T$ .

- Key = edge; priority = weight of edge.
- DELETE-MIN to determine next edge  $e = v-w$  to add to  $T$ .
- If both endpoints  $v$  and  $w$  are marked (both in  $T$ ), disregard.
- Otherwise, let  $w$  be the unmarked vertex (not in  $T$ ):
  - add  $e$  to  $T$  and mark  $w$
  - add to PQ any edge incident to  $w$  ← but don't bother if other endpoint is in  $T$

# Prim's algorithm: lazy implementation

```
public class LazyPrimMST
{
    private boolean[] marked; // MST vertices
    private Queue<Edge> mst;   // MST edges
    private MinPQ<Edge> pq;    // PQ of edges

    public LazyPrimMST(WeightedGraph G)
    {
        pq = new MinPQ<>();
        mst = new Queue<>();
        marked = new boolean[G.V()];
        visit(G, 0); ← assume graph G is connected
    }
}
```

```
while (mst.size() < G.V() - 1)
{
    Edge e = pq.delMin();
    int v = e.either(), w = e.other(v);
    if (marked[v] && marked[w]) continue;
    mst.enqueue(e);
    if (!marked[v]) visit(G, v);
    if (!marked[w]) visit(G, w);
}
```

← repeatedly delete the min-weight edge  $e = v-w$  from PQ

← ignore if both endpoints in tree  $T$

← add edge  $e$  to tree  $T$

← add either  $v$  or  $w$  to tree  $T$

```
private void visit(WeightedGraph G, int v)
{
    marked[v] = true; ← add v to tree T
    for (Edge e : G.adj(v))
        if (!marked[e.other(v)])
            pq.insert(e);
}
```

```
public Iterable<Edge> mst()
{ return mst; }
```

for each edge  $e = v-w$ :  
add  $e$  to PQ if  $w$  not already in  $T$

## Lazy Prim's algorithm: running time

---

**Proposition.** In the worst case, lazy Prim's algorithm computes the MST in  $\Theta(E \log E)$  time and  $\Theta(E)$  extra space.

**Pf.**

- Bottlenecks are PQ operations.
- Each edge is added to PQ at most once.
- Each edge is deleted from PQ at most once.

operation	frequency	time per op
INSERT	$E$	$\log E^\dagger$
DELETE-MIN	$E$	$\log E^\dagger$

$\dagger$  using binary heap

# Prim's algorithm: eager implementation

**Challenge.** Find min-weight edge with exactly one endpoint in  $T$ .

**Observation.** For each vertex  $v$ , need only **min-weight** edge connecting  $v$  to  $T$ .

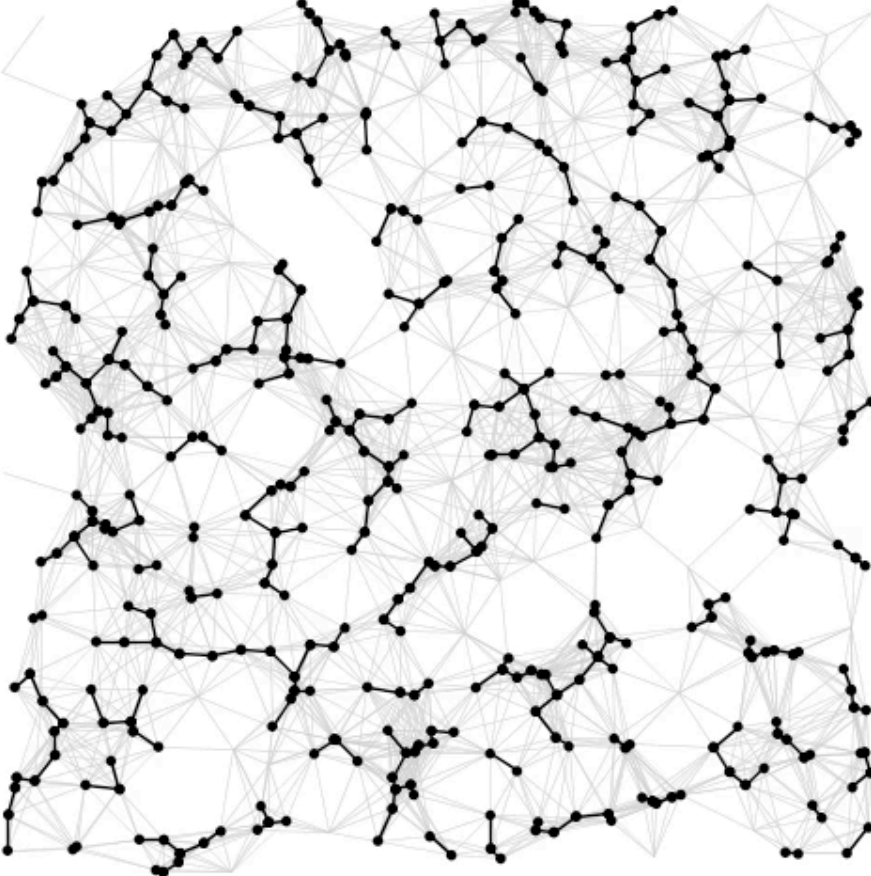

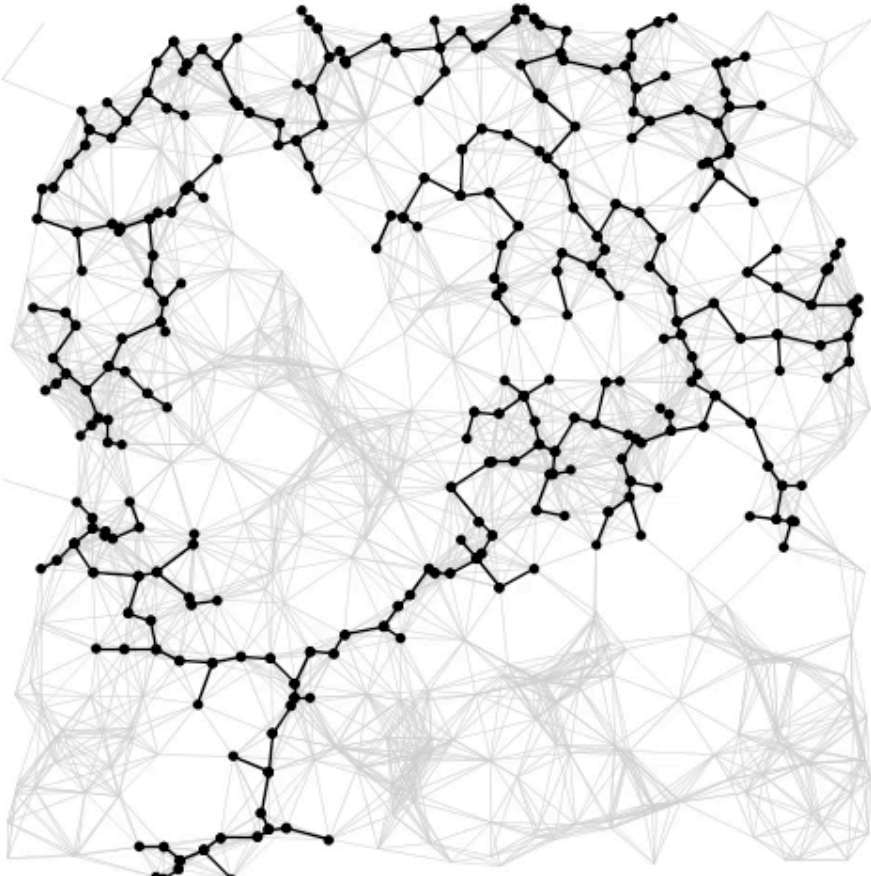

- MST includes at most one edge connecting  $v$  to  $T$ . Why?
- If MST includes such an edge, it must take lightest such edge. Why?

**Impact.** PQ of **vertices**;  $\Theta(V)$  extra space;  $\Theta(E \log V)$  running time in worst case.
