

Introduction to Stochastic Simulation with the Gillespie Method

David Karig
April 18, 2005

Stochastic Systems

- Many systems driven by random, discrete interactions
- Traditional deterministic models may not accurately describe such systems

Example: The Lambda Switch

Virus Decision Dictated by Noise

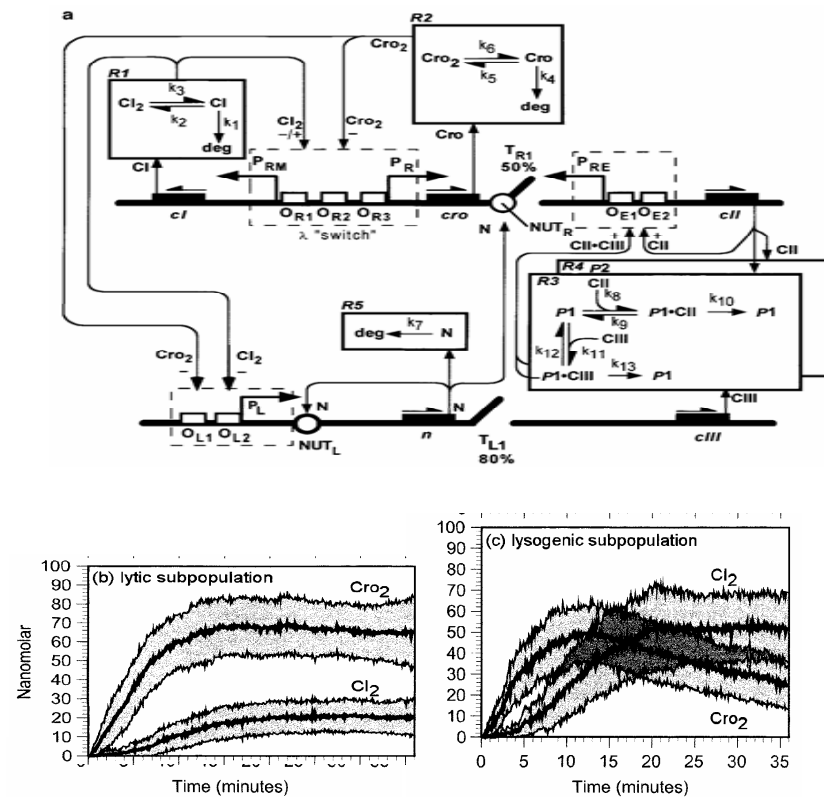

Example: The Lambda Switch

Virus Decision Dictated by Noise

Example: The Lambda Switch

Virus Decision Dictated by Noise

Arkin, Ross, McAdams, *Genetics* (1998)

Outline

- Deterministic rate reaction model
- Gillespie method
- Examples
 - Lambda phage
 - Epidemiology
- Optimizations

Deterministic Model

Reactions:

ODE's:

$$dA/dt = -k_1 * A * B + k_2 * C - k_3 * A$$

$$dB/dt = -k_1 * A * B + k_2 * C + k_3 * A$$

$$dC/dt = k_1 * A * B - k_2 * C - k_4 * C$$

- Given initial conditions, integrate the coupled equations for some period of time

Problem Statement

If we start with N species which can interact through one of M reactions at a given time, *what will be the population levels of species after a given period of time?*

Deterministic Solution

$$dA/dt = -k_1 * A * B + k_2 * C - k_3 * A$$

$$dB/dt = -k_1 * A * B + k_2 * C + k_3 * A$$

$$dC/dt = k_1 * A * B - k_2 * C - k_4 * C$$

- Continuous
- Average kinetic rates represent reaction probabilities

Validity of Deterministic Solution

Validity of Deterministic Solution

Reaction Probabilities

- $c_{\mu} dt$ = average probability that a *particular* combination of reactants will react according to R_{μ} in the next time interval dt
- h_{μ} = number of reactant combinations
- $h_{\mu} c_{\mu} dt = a_{\mu} dt$ = average probability that an R_{μ} reaction will occur somewhere inside V in the next time interval dt

Reaction Probabilities

- $c_\mu dt$ = average probability that a *particular* combination of reactants will react according to R_μ in the next time interval dt
- h_μ = number of reactant combinations
- $h_\mu c_\mu dt = a_\mu dt$ = average probability that an R_μ reaction will occur somewhere inside V in the next time interval dt

X molecules of A
Y molecules of B } $h_1 = XY$ reactant combinations

$XYc_1 dt$ = probability that an R_1 reaction will occur somewhere inside V in the next time interval dt

Exact Stochastic Simulation

- Avoid averaging assumptions
- Probabilistic formulation
 - *When* does next reaction occur?
 - *Which* reaction occurs next?
- Reaction probability density function:

$P(\tau, \mu) d\tau$ = probability at time t that the next reaction is R_μ and occurs in interval $(t+\tau, t+\tau+d\tau)$

System State:

	t	$t+\tau$
A	1	2
B	1	2
C	8	7

Deriving Reaction PDF

$$P(\tau, \mu) d\tau = \underbrace{P_0(\tau)}_{\text{probability that no reaction occurs during } (t, t+\tau)} \underbrace{h_\mu c_\mu d\tau}_{\text{probability that reaction } \mu \text{ occurs during } (t+\tau, t+\tau+d\tau)}$$

Deriving $P_0(\tau)$ for Reaction PDF

- Divide $(t, t+\tau)$ into K subintervals of width ε

- Probability that none of the reactions occur in any of the K subintervals:

$$P_0(\tau) = \left[1 - \sum_{i=1}^M h_i c_i \varepsilon \right]^K = \lim_{K \rightarrow \infty} \left[1 - \frac{\sum_{i=1}^M h_i c_i \tau}{K} \right]^K = e^{-\sum_{i=1}^M h_i c_i \tau}$$

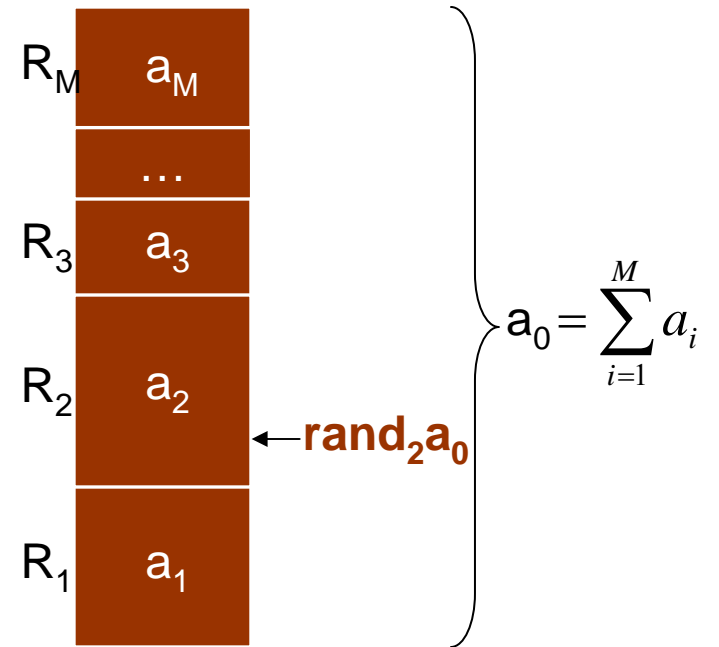

Direct Method for Generating $P(\tau, \mu)$

$$\begin{aligned}
 P(\tau, \mu) &= h_\mu c_\mu P_0(\tau) = h_\mu c_\mu e^{-\sum_{i=1}^M h_i c_i \tau} \\
 &= a_\mu e^{-a_0 \tau} \\
 &= \left(a_0 e^{-a_0 \tau} \right) \left(\frac{a_\mu}{a_0} \right) = \underbrace{P(\tau)}_{\substack{\text{when} \\ \text{next} \\ \text{reaction} \\ \text{occurs}}} \cdot \underbrace{P(\mu|\tau)}_{\substack{\text{which} \\ \text{reaction} \\ \text{occurs}}}
 \end{aligned}$$

Direct Method for Generating $P(\tau, \mu)$

$$\begin{aligned}
 P(\tau, \mu) &= h_\mu c_\mu P_0(\tau) = h_\mu c_\mu e^{-\sum_{i=1}^M h_i c_i \tau} \\
 &= a_\mu e^{-a_0 \tau} \\
 &= \left(a_0 e^{-a_0 \tau} \right) \left(\frac{a_\mu}{a_0} \right) = \underbrace{P(\tau)}_{\substack{\text{when} \\ \text{next} \\ \text{reaction} \\ \text{occurs}}} \cdot \underbrace{P(\mu|\tau)}_{\substack{\text{which} \\ \text{reaction} \\ \text{occurs}}}
 \end{aligned}$$

$$\tau = (1/a_0) \ln(1/\text{rand}_1)$$

μ is the integer for which $\sum_{i=1}^{\mu-1} a_i < \text{rand}_2 a_0 < \sum_{i=1}^{\mu} a_i$

Stochastic Simulation Algorithm

1. Initialization

- Set values of c_μ for the M reactions.
- Set initial population sizes

2. Calculate the M values a_μ and $a_0 = \sum a_\mu$.

3. Generate (τ, μ) based on $P(\tau, \mu)$

4. Adjust population levels according to the reaction R_μ , and increase t by τ

5. Return to Step 2

Lambda Phage Developmental Pathway

Arkin, Ross, McAdams, *Genetics* (1998)

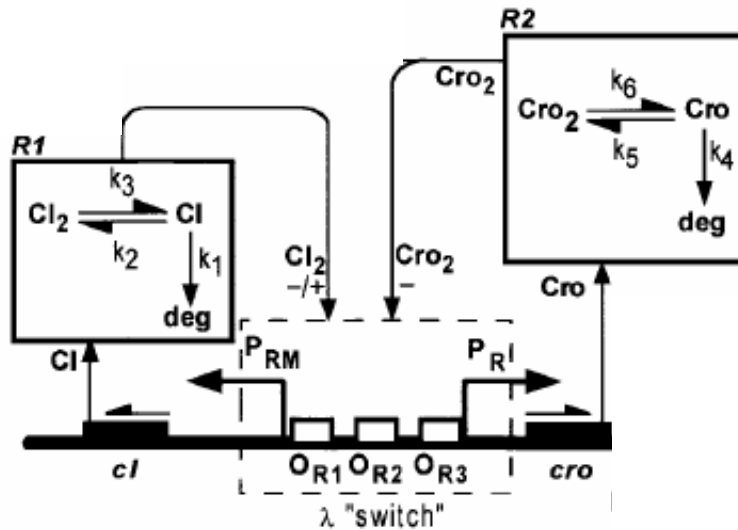

- Regulatory circuit exploits stochastic noise to produce different outcomes
- Stochastic model can predict statistics of regulatory outcomes

Lambda Phage: Regulatory Circuit

- CI and Cro competitively bind O_{R1} , O_{R2} , O_{R3}
- Cro represses P_R and P_{RM}
- CI represses P_R , can activate P_{RM}

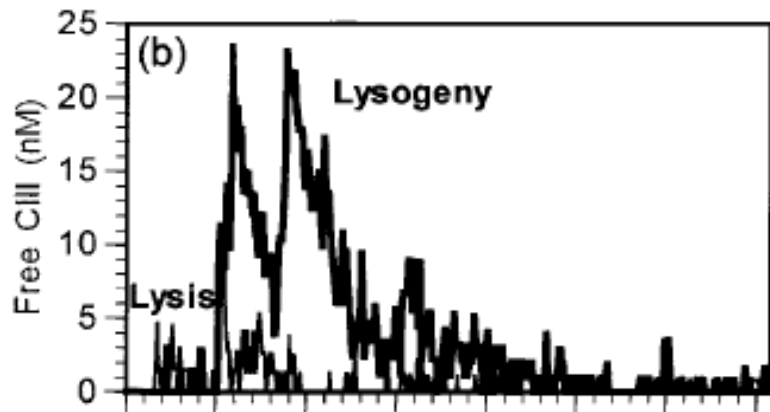

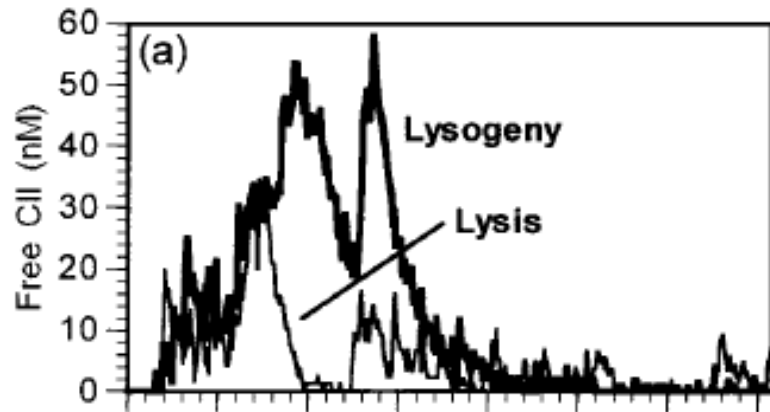

Lambda Phage: Regulatory Circuit

- Cl and Cro competitively bind O_{R1} , O_{R2} , O_{R3}
- Cro represses P_R and P_{RM}
- Cl represses P_R , can activate P_{RM}

Time Evolution of Two Runs

Epidemiology Example

Evaluation of Stochastic Simulation

- **Advantages**
 - continuous time, discrete population changes
 - captures effects of noise
 - simple implementation
 - small memory requirements
- **Disadvantages**
 - CPU intensive
 - typically must simulate many runs
 - must use good random number generator
 - periodicity affects size of simulation
 - resolution limits range of probabilities

Computational Requirements

- Memory ($N + 2M + 1$)
 - N species populations
 - c and a values for each of M reactions; a_0
- Total time scales with number of reactions that occur
- Operations per reaction:

Generate 2 random numbers	
Calculate a_0	} $O(M)$
Calculate τ	
Search μ	} $O(M)$
Calculate a values	

Optimized Direct Method (ODM)

Y. Cao, H. Li, L. Petzold. 2004. J. Chem. Phys. 121:4059-4067

- Reduce cost of searching for index μ
- Observation: Reactions are typically multiscale in a large system. Subset will frequently occur.
- Sort index of reactions based on how often they occur

$$\sum_{i=1}^{\mu-1} a_i < \text{rand}_2 a_0 < \sum_{i=1}^{\mu} a_i$$

Optimized Direct Method (ODM)

- Reduce cost of calculating all a_μ
- Dependency graph
- Reduce cost of summing all a_μ to calculate a_0
- Modify a_0 by subtracting old values, adding new

Gibson and Bruck, 2000

Conclusion

- Provides means of studying role of noise in complex systems
- Can predict statistics (Lambda phage)
- Can depict behavior that deterministic simulations do not capture (epidemiology example)
- Enhancing performance an active area of investigation

Comparing to Experimental Results

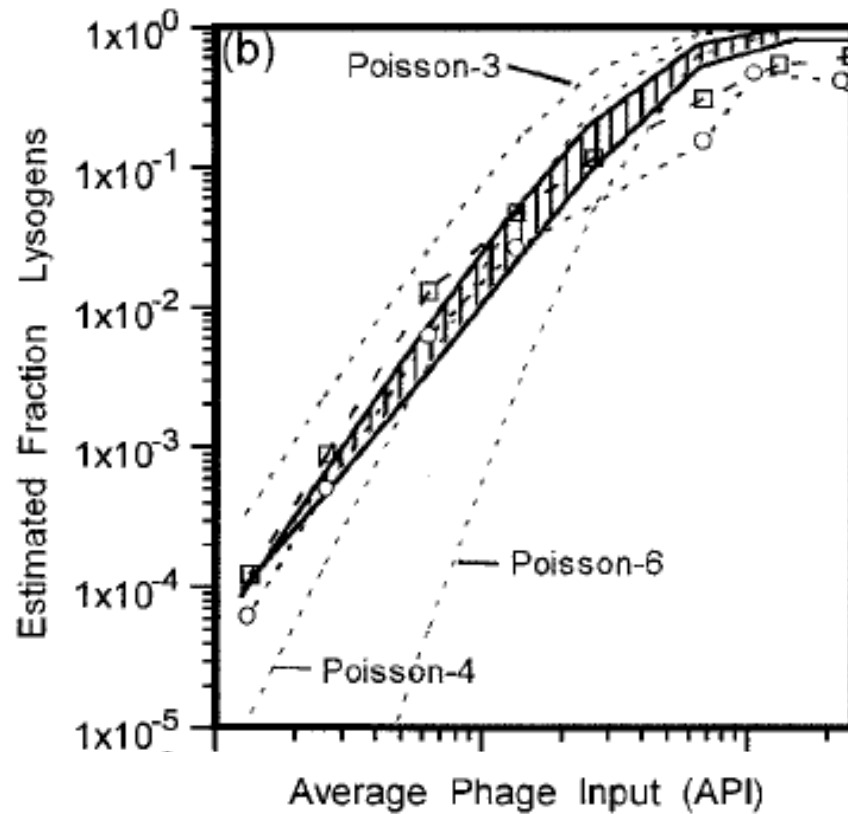

- Compare predicted percent lysogenization to experimental results at different infection levels
- Average phage input (API) = ratio of phage particles to cells at time of infection
- Multiplicity of infection (MOI) = phage particles per cell
- Poisson probability that a given cell will be infected with MOI=M when API=A

$$P(M, A) = \frac{A^M}{M!} e^{-A}$$

- Expected fraction of lysogens:

$$F_{lysogens}(A) = \sum_M P(M, A) \cdot F(M)$$

Comparing to Experimental Results

Example (deterministic assumptions)

Average rate of R_1 in dt per unit volume:

$$\frac{\langle X_1 X_2 c_1 \rangle}{V} = \frac{\langle X_1 X_2 \rangle c_1}{V}$$

Using concentrations $x_i = X_i/V$ and dividing by density of reactants:

$$k_1 = \frac{\langle x_1 x_2 \rangle c_1 V}{\langle x_1 \rangle \langle x_2 \rangle}$$

Deterministic assumption:

$$k_1 = c_1 V$$

Master equation

$$\frac{\partial}{\partial t} P(X_1, \dots, X_N; t) = \sum_{\mu=1}^M [B_{\mu} - a_{\mu} P(X_1, \dots, X_N; t)]$$

- $B_{\mu} dt =$ probability that single R reaction brings us to state X_1, \dots, X_N
- $a_{\mu} dt = h_{\mu} c_{\mu} dt$, where h_{μ} is the number of reactant combinations
- Often difficult to solve analytically and even numerically
- \rightarrow Instead simulate individual trajectories using Monte Carlo algorithm
