DATA STRUCTURES I, II, III, AND IV

I. Amortized Analysis
II. Binary and Binomial Heaps
III. Fibonacci Heaps
IV. Union–Find

Appetizer

Goal. Design a data structure to support all operations in \( O(1) \) time.
- INIT(n): create and return an initialized array (all zero) of length \( n \).
- READ(A, i): return \( i \)th element of array.
- WRITE(A, i, value): set \( i \)th element of array to value.

Assumptions.
- Can MALLOC an uninitialized array of length \( n \) in \( O(1) \) time.
- Given an array, can read or write \( i \)th element in \( O(1) \) time.

Remark. An array does INIT in \( O(n) \) time and READ and WRITE in \( O(1) \) time.

Data structures

Static problems. Given an input, produce an output.
Ex. Sorting, FFT, edit distance, shortest paths, MST, max-flow, ...

Dynamic problems. Given a sequence of operations (given one at a time), produce a sequence of outputs.
Ex. Stack, queue, priority queue, symbol table, union-find, ....

Algorithm. Step-by-step procedure to solve a problem.
Data structure. Way to store and organize data.
Ex. Array, linked list, binary heap, binary search tree, hash table, ...

データ構造

静的問題：与えられた入力に対して、出力を生成する。
例：ソーティング、FFT、エディット距離、最短経路、MST、Max-flow、...

動的問題：一時的な順序（一つずつ与えられる）で一連の操作に従って、一連の出力を出力する。
例：スタック、キュー、優先度キュー、記号表、union-find、....

アルゴリズム：問題を解くための手順。
データ構造：データを保存・管理する方法。
例：配列、連結リスト、二分ヒープ、二分探索ツリー、ハッシュ表、...
**Appetizer**

**Theorem.** \( A[i] \) is initialized iff both \( 1 \leq B[i] \leq k \) and \( C[B[i]] = i \).

**Pf.**

- Suppose \( A[i] \) is uninitialized.
- If \( B[i] < 1 \) or \( B[i] > k \), then \( A[i] \) clearly uninitialized.
- If \( 1 \leq B[i] \leq k \) by coincidence, then we still can't have \( C[B[i]] = i \) because none of the entries \( C[1..k] \) can equal \( i \).

**Amortized Analysis**

- binary counter
- multi-pop stack
- dynamic table
Amortized analysis

**Worst-case analysis.** Determine worst-case running time of a data structure operation as function of the input size. can be too pessimistic if the only way to encounter an expensive operation is if there were lots of previous cheap operations

Amortized analysis. Determine worst-case running time of a sequence of data structure operations as a function of the input size.

Ex. Starting from an empty stack implemented with a dynamic table, any sequence of $n$ push and pop operations takes $O(n)$ time in the worst case.

---

**Amortized Analysis**

- **binary counter**
- **multi-pop stack**
- **dynamic table**

---

**Binary counter**

**Goal.** Increment a $k$-bit binary counter (mod $2^k$).

**Representation.** $a_j = j^\text{th}$ least significant bit of counter.

Theorem. Starting from the zero counter, a sequence of $n$ INCREMENT operations flips $O(nk)$ bits.

Pf. At most $k$ bits flipped per increment.

Binary counter: aggregate method

Starting from the zero counter, in a sequence of $n$ INCREMENT operations:

- Bit 0 flips $n$ times.
- Bit 1 flips $\lceil n/2 \rceil$ times.
- Bit 2 flips $\lceil n/4 \rceil$ times.
- ...

Theorem. Starting from the zero counter, a sequence of $n$ INCREMENT operations flips $O(n)$ bits.

Pf.

- Bit $j$ flips $\lceil n/2^j \rceil$ times.
- The total number of bits flipped is $\sum_{j=0}^{k-1} \lceil n/2^j \rceil < n \sum_{j=0}^{\infty} 1/2^j = 2n$

Remark. Theorem may be false if initial counter is not zero.

Aggregate method (brute force)

Aggregate method. Sum up sequence of operations, weighted by their cost.

Accounting method (banker’s method)

Assign (potentially) different charges to each operation.

- $D_i$ = data structure after $i^{th}$ operation.
- $c_i$ = actual cost of $i^{th}$ operation.
- $\hat{c}_i$ = amortized cost of $i^{th}$ operation = amount we charge operation $i$.
- When $\hat{c}_i > c_i$, we store credits in data structure $D_i$ to pay for future ops; when $\hat{c}_i < c_i$, we consume credits in data structure $D_i$.
- Initial data structure $D_0$ starts with zero credits.

Key invariant. The total number of credits in the data structure $\geq 0$.

\[ \sum_{i=1}^{\infty} \hat{c}_i - \sum_{i=1}^{\infty} c_i \geq 0 \]
Accounting method (banker’s method)

Assign (potentially) different charges to each operation.
- $D_i =$ data structure after $i$th operation.
- $c_i =$ actual cost of $i$th operation.
- $\hat{c}_i =$ amortized cost of $i$th operation = amount we charge operation $i$.
- When $\hat{c}_i > c_i$, we store credits in data structure $D_i$ to pay for future ops; when $\hat{c}_i < c_i$, we consume credits in data structure $D_i$.
- Initial data structure $D_0$ starts with zero credits.

Key invariant. The total number of credits in the data structure $\geq 0$.
$$\sum_{i=1}^{n} \hat{c}_i - \sum_{i=1}^{n} c_i \geq 0$$

Theorem. Starting from the initial data structure $D_0$, the total actual cost of any sequence of $n$ operations is at most the sum of the amortized costs.

Pf. The amortized cost of the sequence of operations is: $\sum_{i=1}^{n} \hat{c}_i \geq \sum_{i=1}^{n} c_i$.

Intuition. Measure running time in terms of credits (time = money).

Binary counter: accounting method

Credits. One credit pays for a bit flip.

Invariant. Each 1 bit has one credit; each 0 bit has zero credits.

Accounting.
- Flip bit $j$ from 0 to 1: charge two credits (use one and save one in bit $j$).
- Flip bit $j$ from 1 to 0: pay for it with the one credit saved in bit $j$.

Increment

Binary counter: accounting method

Credits. One credit pays for a bit flip.
Invariant. Each 1 bit has one credit; each 0 bit has zero credits.

Accounting.
• Flip bit $j$ from 0 to 1: charge two credits (use one and save one in bit $j$).
• Flip bit $j$ from 1 to 0: pay for it with the one credit saved in bit $j$.

Theorem. Starting from the zero counter, a sequence of $n$ increment operations flips $O(n)$ bits.

Pf. Each increment operation flips at most one 0 bit to a 1 bit (so the total amortized cost is at most $2n$).
• The invariant is maintained. ⇒ number of credits in each bit $\geq 0$.

Potential method (physicist’s method)

Potential function. $\Phi(D_i)$ maps each data structure $D_i$ to a real number s.t.:
• $\Phi(D_0) = 0$.
• $\Phi(D_i) \geq 0$ for each data structure $D_i$.

Actual and amortized costs.
• $c_i = $ actual cost of $i^{th}$ operation.
• $\hat{c}_i = c_i + \Phi(D_i) - \Phi(D_{i-1}) = $ amortized cost of $i^{th}$ operation.

Theorem. Starting from the initial data structure $D_0$, the total actual cost of any sequence of $n$ operations is at most the sum of the amortized costs.

Pf. The amortized cost of the sequence of operations is:
$$\sum_{i=1}^{n} \hat{c}_i = \sum_{i=1}^{n} (c_i + \Phi(D_i) - \Phi(D_{i-1}))$$
$$= \sum_{i=1}^{n} c_i + \Phi(D_n) - \Phi(D_0)$$
$$\geq \sum_{i=1}^{n} c_i$$

Binary counter: potential method

Potential function. Let $\Phi(D) =$ number of 1 bits in the binary counter $D$.
• $\Phi(D_0) = 0$.
• $\Phi(D) \geq 0$ for each $D_i$.
Binary counter: potential method

**Potential function.** Let $\Phi(D)$ = number of 1 bits in the binary counter $D$.
- $\Phi(D_0) = 0$.
- $\Phi(D_i) \geq 0$ for each $D_i$.

Increment

<table>
<thead>
<tr>

<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

**Theorem.** Starting from the zero counter, a sequence of $n$ INCREMENT operations flips $O(n)$ bits.

**Pf.**
- Suppose that the $i$th increment operation flips $t_i$ bits from 1 to 0.
- The actual cost $c_i = t_i + 1$. [operation sets one bit to 1 (unless counter resets to zero)]
- The amortized cost $\bar{c}_i = c_i + \Phi(D_{i−1}) − \Phi(D_i)$
  $\leq c_i + 1 - t_i$
  $\leq 2$. ●

Famous potential functions

**Fibonacci heaps.** $\Phi(H) = 2 \text{trees}(H) + 2 \text{marks}(H)$

**Splay trees.** $\Phi(T) = \sum_{x \in T} \lfloor \log_2 \text{size}(x) \rfloor$

**Move-to-front.** $\Phi(L) = 2 \text{inversions}(L, L^*)$

**Preflow–push.** $\Phi(f) = \sum_{v : \text{excess}(v) > 0} \text{height}(v)$

**Red-black trees.** $\Phi(T) = \sum_{x \in T} w(x)$

$w(x) = \begin{cases} 
0 & \text{if } x \text{ is red} \\
1 & \text{if } x \text{ is black and has no red children} \\
0 & \text{if } x \text{ is black and has one red child} \\
2 & \text{if } x \text{ is black and has two red children}
\end{cases}$
**Amortized Analysis**

- binary counter
- multi-pop stack
- dynamic table

### Multipop stack

**Goal.** Support operations on a set of elements:
- \( \text{PUSH}(S, x) \): push object \( x \) onto stack \( S \).
- \( \text{POP}(S) \): remove and return the most-recently added object.
- \( \text{MULTI-POP}(S, k) \): remove the most-recently added \( k \) objects.

**Theorem.** Starting from an empty stack, any intermixed sequence of \( n \) \( \text{PUSH} \), \( \text{POP} \), and \( \text{MULTI-POP} \) operations takes \( O(n^2) \) time.

**Pf.**
- Use a singly-linked list.
- \( \text{POP} \) and \( \text{PUSH} \) take \( O(1) \) time each.
- \( \text{MULTI-POP} \) takes \( O(n) \) time.

---

**Multipop stack: aggregate method**

**Goal.** Support operations on a set of elements:
- \( \text{PUSH}(S, x) \): push object \( x \) onto stack \( S \).
- \( \text{POP}(S) \): remove and return the most-recently added object.
- \( \text{MULTI-POP}(S, k) \): remove the most-recently added \( k \) objects.

**Theorem.** Starting from an empty stack, any intermixed sequence of \( n \) \( \text{PUSH} \), \( \text{POP} \), and \( \text{MULTI-POP} \) operations takes \( O(n) \) time.

**Pf.**
- An object is popped at most once for each time it is pushed onto stack.
- There are \( \leq n \) \( \text{PUSH} \) operations.
- Thus, there are \( \leq n \) \( \text{POP} \) operations (including those made within \( \text{MULTI-POP} \)).
Multipop stack: accounting method

**Credits.** One credit pays for a push or pop.

**Accounting.**
- PUSH($S$, $x$): charge two credits.
- use one credit to pay for pushing $x$ now
- store one credit to pay for popping $x$ at some point in the future
- No other operation is charged a credit.

**Theorem.** Starting from an empty stack, any intermixed sequence of $n$ PUSH, POP, and MULTI-POP operations takes $O(n)$ time.

**Pf.** The algorithm maintains the invariant that every object remaining on the stack has 1 credit $\Rightarrow$ number of credits in data structure $\geq 0$.

---

Multipop stack: potential method

**Potential function.** Let $\Phi(D) =$ number of objects currently on the stack.
- $\Phi(D_0) = 0$.
- $\Phi(D) \geq 0$ for each $D_i$.

**Theorem.** Starting from an empty stack, any intermixed sequence of $n$ PUSH, POP, and MULTI-POP operations takes $O(n)$ time.

**Pf.** [Case 1: push]
- Suppose that the $i^{th}$ operation is a PUSH.
- The actual cost $c_i = 1$.
- The amortized cost $\hat{c}_i = c_i + \Phi(D_i) - \Phi(D_{i-1}) = 1 + 1 = 2$.

---

Multipop stack: potential method

**Potential function.** Let $\Phi(D) =$ number of objects currently on the stack.
- $\Phi(D_0) = 0$.
- $\Phi(D) \geq 0$ for each $D_i$.

**Theorem.** Starting from an empty stack, any intermixed sequence of $n$ PUSH, POP, and MULTI-POP operations takes $O(n)$ time.

**Pf.** [Case 2: pop]
- Suppose that the $i^{th}$ operation is a POP.
- The actual cost $c_i = 1$.
- The amortized cost $\hat{c}_i = c_i + \Phi(D_i) - \Phi(D_{i-1}) = 1 - 1 = 0$.

---

Multipop stack: potential method

**Potential function.** Let $\Phi(D) =$ number of objects currently on the stack.
- $\Phi(D_0) = 0$.
- $\Phi(D) \geq 0$ for each $D_i$.

**Theorem.** Starting from an empty stack, any intermixed sequence of $n$ PUSH, POP, and MULTI-POP operations takes $O(n)$ time.

**Pf.** [Case 3: multi-pop]
- Suppose that the $i^{th}$ operation is a MULTI-POP of $k$ objects.
- The actual cost $c_i = k$.
- The amortized cost $\hat{c}_i = c_i + \Phi(D_i) - \Phi(D_{i-1}) = k - k = 0$. •
### Amortized Analysis

- binary counter
- multi-pop stack
- dynamic table

#### Dynamic Table

**Goal.** Store items in a table (e.g., for hash table, binary heap).
- Two operations: **INSERT** and **DELETE**.
  - too many items inserted ⇒ **expand** table.
  - too many items deleted ⇒ **contract** table.
- Requirement: if table contains \( m \) items, then space = \( \Theta(m) \).

**Theorem.** Starting from an empty dynamic table, any intermixed sequence of \( n \) **INSERT** and **DELETE** operations takes \( O(n^2) \) time.

**Pf.** A single **INSERT** or **DELETE** takes \( O(n) \) time. ●

#### Dynamic Table: insert only

- Initialize empty table of capacity 1.
- **INSERT**: if table is full, first copy all items to a table of twice the capacity.

<table>
<thead>
<tr>
<th>insert</th>
<th>old capacity</th>
<th>new capacity</th>
<th>insert cost</th>
<th>copy cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>–</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>4</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>4</td>
<td>1</td>
<td>–</td>
</tr>
<tr>
<td>5</td>
<td>4</td>
<td>8</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>6</td>
<td>8</td>
<td>8</td>
<td>1</td>
<td>–</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>8</td>
<td>1</td>
<td>–</td>
</tr>
<tr>
<td>8</td>
<td>8</td>
<td>8</td>
<td>1</td>
<td>–</td>
</tr>
<tr>
<td>9</td>
<td>8</td>
<td>16</td>
<td>1</td>
<td>8</td>
</tr>
<tr>
<td>⋮</td>
<td>⋮</td>
<td>⋮</td>
<td>⋮</td>
<td>⋮</td>
</tr>
</tbody>
</table>

**Cost model.** Number of items written (due to insertion or copy).

#### Dynamic Table: insert only (aggregate method)

**Theorem.** [via aggregate method] Starting from an empty dynamic table, any sequence of \( n \) **INSERT** operations takes \( O(n) \) time.

**Pf.** Let \( c_i \) denote the cost of the \( i \)th insertion.

\[
c_i = \begin{cases} 
  i & \text{if } i - 1 \text{ is an exact power of 2} \\
  1 & \text{otherwise}
\end{cases}
\]

Starting from empty table, the cost of a sequence of \( n \) **INSERT** operations is:

\[
\sum_{i=1}^{n} c_i \leq n + \sum_{j=0}^{\lfloor \lg n \rfloor} 2^j < n + 2n = 3n \quad \blacksquare
\]
Dynamic table: insert only (accounting method)

WLOG, can assume the table fills from left to right.

Theorem. [via accounting method] Starting from an empty dynamic table, any sequence of $n$ INSERT operations takes $O(n)$ time.

Pf. The algorithm maintains the invariant that there are 2 credits with each item in right half of table.

1. When table doubles, one-half of the items in the table have 2 credits.
2. This pays for the work needed to double the table. 

Dynamic table: insert only (potential method)

Theorem. [via potential method] Starting from an empty dynamic table, any sequence of $n$ INSERT operations takes $O(n)$ time.

Pf. Let $\Phi(D_i) = 2 \cdot \text{size}(D_i) - \text{capacity}(D_i)$.

Case 1. [does not trigger expansion] $\text{size}(D_i) \leq \text{capacity}(D_{i-1})$.

1. Actual cost $c_i = 1$.
2. $\Phi(D_i) - \Phi(D_{i-1}) = 2$.
3. Amortized costs $\hat{c}_i = c_i + \Phi(D_i) - \Phi(D_{i-1}) = 1 + 2 = 3$.

Case 2. [triggers expansion] $\text{size}(D_i) = 1 + \text{capacity}(D_{i-1})$.

1. Actual cost $c_i = 1 + \text{capacity}(D_{i-1})$.
2. $\Phi(D_i) - \Phi(D_{i-1}) = 2 - \text{capacity}(D_i) + \text{capacity}(D_{i-1}) = 2 - \text{capacity}(D_{i-1})$.
3. Amortized costs $\hat{c}_i = c_i + \Phi(D_i) - \Phi(D_{i-1}) = 1 + 2 = 3$.  

Dynamic table: doubling and halving

Thrashing.
- Initialize table to be of fixed capacity, say 1.
- INSERT: if table is full, expand to a table of twice the capacity.
- DELETE: if table is ½-full, contract to a table of half the capacity.

Efficient solution.
- Initialize table to be of fixed capacity, say 1.
- INSERT: if table is full, expand to a table of twice the capacity.
- DELETE: if table is ¼-full, contract to a table of half the capacity.

Memory usage. A dynamic table uses $O(n)$ memory to store $n$ items.

Pf. Table is always at least ¼-full (provided it is not empty).

Dynamic table: insert and delete (accounting method)

Accounting.
- INSERT: charge 3 credits (1 credit for insert; save 2 with new item).
- DELETE: charge 2 credits (1 credit to delete, save 1 in emptied slot).

Theorem. [via accounting method] Starting from an empty dynamic table, any intermixed sequence of $n$ INSERT and DELETE operations takes $O(n)$ time.

Pf. The algorithm maintains the invariant that there are 2 credits with each item in the right half of table; 1 credit with each empty slot in the left half.
- When table doubles, each item in right half of table has 2 credits.
- When table halves, each empty slot in left half of table has 1 credit.

Dynamic table: insert and delete (potential method)

Theorem. [via potential method] Starting from an empty dynamic table, any intermixed sequence of $n$ INSERT and DELETE operations takes $O(n)$ time.

Pf sketch.
- Let $\alpha(D_i) = \frac{\text{size}(D_i)}{\text{capacity}(D_i)}$.
- Define $\Phi(D_i) = \begin{cases} 2\text{size}(D_i) - \text{capacity}(D_i) & \text{if } \alpha(D_i) \geq 1/2 \\ \frac{1}{2}\text{capacity}(D_i) - \text{size}(D_i) & \text{if } \alpha(D_i) < 1/2 \end{cases}$

- When $\alpha(D) = 1/2$, $\Phi(D) = 0$. [zero potential after resizing]
- When $\alpha(D) = 1$, $\Phi(D) = \text{size}(D_i)$. [can pay for expansion]
- When $\alpha(D) = 1/4$, $\Phi(D) = \text{size}(D_i)$. [can pay for contraction]
...
